This dissertation is dedicated to my lovely parents, my wife Lana, my kids (Razzan and Aamin) and to who taught me a letter

ACKNOWLEDGMENTS

My first and foremost thanks to Almighty Allah for giving me strength, power and patience to complete my postgraduate study successfully. My special thanks to King Fahd University of Petroleum and Minerals (KFUPM) for providing me an opportunity to achieve my Ph.D. degree in Chemistry Department.

My appreciation connected to the formal Chairman Dr. Abdullah Al-Hamadan for his great efforts that enable me to complete my study. Also, I would like to express my special thanks to current Chairman Dr. Abdulaziz Al-Saadi and Graduate Coordinator Prof. Bassam El-Ali for their supports and facilities provided by Chemistry Department.

I would like to connect my gratitude and special thanks to my advisor Prof. Anvar Husein A. Isab for his encouragement, he accepted me when I was in my sixth semester. I want to thank him for his support, guidance and wisdom words without his enthusiasm and dedication this work could not be possible by Allah's willing.

I wish to appreciate and acknowledge my committee members Dr. Mohammed Fettouhi, Dr. Hassan Al-Muallem, Prof. Mohammed I. M. Wazeer and Prof. Akhtar Naqvi for their help, advice, guidance and revision of my dissertation. Further, I need to give my thanks to Mr. Mohammed Arab and Mr. Mansour Al-Zaki for their support to use IR, Elemental analyzer, and NMR. Heartfelt thanks to Dr. Musa M. Musa and Dr. Abdel-Nasser Kawde for their help beside a permission to do a part of my work in their labs. Many thanks to Dr. Mohammed Altaf for his help and advice.

Thank you kindly, my parents for your sacrifices, my wife Lana, my kids Razzan and Aamin for your prayers, support, and advice. Thanks to Sudanese Students in KFUPM.

LIST OF FIGURES	xvi
LIST OF ABBREVIATIONS	xxvi
ABSTRACT	xxviii
ملخص الرسالة.....	xxxix
CHAPTER 1.....	1
INTRODUCTION	1
1.1. Gold(III) complexes.....	1
1.2 Gold(I) complexes.....	3
1.3 RESEARCH OBJECTIVES	6
CHAPTER 2.....	8
LITERATURE REVIEW	8
2.1. Gold(III) complexes	8
2.2 Gold(I) Complexes	17
2.2.1 Complexes formed from (P, S, Se) donor ligands	17
2.2.2 Complexes formed from (P, C, N) donor ligands.....	22
CHAPTER 3.....	26
SYNTHESIS, ANTI-CANCER EVALUATION OF NEW MIXED-LIGAND GOLD(I) COMPLEXES WITH DITHIOCARBAMATES AND PHOSPHINES	26
3.1 EXPERIMENTAL SECTION.....	26

3.2 Synthesis of binuclear Gold(I) complexes with mixed bis-phosphine and dithiocarbamate ligands	27
3.2.1 [Au ₂ ((1R,2R)-N,N-Bis[2-(diphenylphosphino)benzyl]cyclohexane-1,2-diamine)Cl ₂] with dialkyl and diaryldithiocarbamate ligands (1-5).....	27
3.2.2 [Au ₂ (Bis[(2-diphenylphosphino)ethyl]ammonium chloride)Cl ₂] with dialkyl and diaryldithiocarbamates (6-9)	32
3.2.3 [Au ₂ (Bis[2-(dicyclophosphino)ethyl]amine)Cl ₂] with dialkyl and diaryldithiocarbamates (10-13).....	36
3.2.4 [Au ₂ ((1S,2S)-N,N-Bis[2-(diphenylphosphino)benzyl]cyclohexane-1,2-diamine)Cl ₂] with dialkyl and diaryldithiocarbamates (14-17).....	39
3.3 Synthesis of gold(I) complexes with mono-phosphine and dithiocarbamate ligand.	42
3.3.1 Chlorido(2-(diphenylphosphino)ethylamine)Au(I) with dialkyl and dibenzyl-dithiocarbamates (18-22)	42
3.3.2 Chlorido((1R,2R)-2-(diphenylphosphino)-2,3-dihydro-1H-inden-1-amine)Au(I) with dialkyl and dibenzyl-dithiocarbamate complexes (23-26)	45
3.3.3 Chlorido(1R,2R)-2-(diphenylphosphino)-1-aminocyclohexane)Au(I) with dialkyl and dibenzyl-dithiocarbamates complexes (27-30).....	48
3.3.4 Chlorido(2-(di- <i>i</i> -propylphosphino)ethylamine)Au(I) with dialkyl and dibenzyl-dithiocarbamates complexes (31-34)	51
3.3.5 Gold(I) with mixed tri(<i>o</i> -methoxyphenyl)phosphine and triphenylphosphine complexes (35-37).....	54
3.4 Single crystal structure determination	56
3.5 MTT assay for in vitro cytotoxicity of gold(I) complexes	56
3.6 Results and Discussion	58
3.6.1 Gold(I) complexes with mixed bis-phosphine and dithiocarbamates ligands (2-17).....	58

3.6.1.1 Spectroscopic analysis	58
3.6.2.2 Gold(I) phosphine complexes (35-37)	73
3.6.3 Single crystal X-ray structure of complex 27	74
3.6.4 <i>In vitro</i> cytotoxic activities of gold(I) monophosphine complexes (18-22, 35 and 37).....	77
CHAPTER 4.....	81
SYNTHESIS, CHARACTERIZATION AND <i>IN VITRO</i> CYTOTOXIC EVALUATION OF GOLD(I) CARBENE COMPLEXES WITH SELONE LIGANDS	81
4.1 Introduction.....	81
4.2. Experimental Section	82
4.2.1 Materials and Instrumentation	82
4.2.2 Synthesis of gold(I) carbene complexes with selones (39-50).....	83
4.3 Results and Discussion	89
4.3.1 Spectroscopic characterizations.....	89
4.3.2 Single crystal X-ray structure determination	97
4.3.3 <i>In vitro</i> cytotoxic activities of gold(I) complexes (38-50).....	104
CHAPTER 5.....	110
SYNTHESIS AND CHARACTERIZATION OF (TRI-TERT-BUTYLPHOSPHINO)GOLD(I) THIONE COMPLEXES	110
5.1 Introduction	110
5.2 Experimental Section	111
5.2.1 Materials and instrumentation.....	111
5.2.2 Synthesis of (tri-tert-butylphosphino)gold(I) thione complexes (52-55)	111
5.3 Results and discussion	113
5.3.1 Spectroscopic characterization.....	113

5.3.2 Signal crystal X-ray structure determination	117
CHAPTER 6.....	123
SYNTHESIS AND CHARACTERIZATION OF GOLD(I) CARBENE COMPLEXES WITH MONO AND BIS-PHOSPHINE LIGANDS.....	123
6.1 Introduction	123
6.2 Experimental Section.....	123
6.2.1 Materials and Instrumentation	123
6.2.2 Synthesis of gold(I) N-heterocyclic carbene with mono and bis-phosphine complexes (56-65)	124
6.3 Results and Discussion.....	131
6.3.1 Spectroscopic Characterization.....	131
6.3.2 Signal crystal X-ray structure	137
CHAPTER 7.....	145
SPECTROSCOPIC STUDIES OF INTERACTIONS OF THE POTENTIAL ANTICANCER AGENTS $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ AND $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ WITH BIOLOGICALLY RELEVANT THIONES	145
7.1 Introduction.	145
7.2 Experimental Section	147
7.2.1 Materials and Instrumentation.....	147
7.2.2 Spectroscopic techniques	147
7.2.3 Electrochemical technique	148
7.2.4 Synthesis of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$	148
7.2.5 Synthesis of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$	148
7.2.6 Kinetic Measurements	149
7.3 Results and Discussion	149

7.3.1 Interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with enriched Tu and DIAZ.....	149
7.3.2 Kinetic Data.....	164
CHAPTER 8.....	183
NMR AND KINETIC STUDIES OF THE INTERACTION OF $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ AND $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ WITH POTASSIUM CYANIDE IN AQUEOUS SOLUTION	183
8.1 Introduction	183
8.2 Experimental section.....	185

ABSTRACT

Name: Adam Ahmed Abdallah Sulaiman

Title of Study: Synthesis, Anti-Cancer Evaluation of New Mixed-Ligand Gold(I) Complexes with Dithiocarbamates and Phosphines, and Interaction Study of Gold(III)-1,2-Diaminocyclohexane Complexes with Some Biomolecules.

Major Field: Chemistry

Date of Degree: May, 2016

Recent advancement in the field of drug formulation and discovery of gold(I) compounds is leading to the innovation of new and unusual gold(I) molecules with linear structure and geometry around the cation. The gold(I) dithiocarbamate complexes, (**2-17**), (**18-22**), (**23-26**), (**27-30**) and (**31-34**), type $[\text{Au}(\text{R}_3\text{P})(\text{R}_2\text{NCS}_2)]$ (where R_2 = dimethyl, diethyl and dibenzyl) were prepared by the reaction of R_3PAuCl compound with sodium dimethyldithiocarbamate monohydrate and sodium diethyl dithiocarbamate trihydrate and dibenzyl dithiocarbamate, respectively. The precursors have been prepared by the reaction of $(\text{CH}_3)_2\text{SAuCl}$ (**1**) with equimolar amount of R_3P . In addition, the complexes of gold(I) phosphine (**35-37**), gold(I) carbene (**38-50**), gold(I) thione (**51-55**) and gold(I) carbene (**56-65**) have been prepared. These complexes were characterized by FT-IR, ^1H , ^{13}C , ^{31}P , ^{77}Se NMR spectroscopy and elemental analysis. Complexes **27**, **39**, **44**, **46**, **48**, **49**, **54**, **55**, **56**, **61**, **63** and **65** were characterized by X-ray diffraction analysis, showing linear geometrical structure around gold center atom. Gold(I) complex (**20-22**) (IC_{50}

19.56 \pm 0.85, 29.25 \pm 1.81 and 34.42 \pm 1.02 μ M) showed potent *in vitro* cytotoxicity one-to-two fold higher than *cisplatin* (IC₅₀ 42.2 \pm 2.01 μ M) against A549 (human lung carcinoma). Furthermore, complex **48** (IC₅₀ 27.97 \pm 1.67) showed better *in vitro* cytotoxicity than *cisplatin* (IC₅₀ 32.04 \pm 2.12 μ M) against HCCT15. All other studied complexes exhibited similar and moderate to lower *in vitro* cytotoxicity against A549, HCT15 (human colon cancer) and HeLa (human cervical cancer) cell lines.

The interactions of the synthesized [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ complexes, (DACH=*cis*-1,2-diaminocyclohexane), with enriched (¹³C, ¹⁵N) thiourea and 1,3-diazinane-2-thione ligands were investigated. The progress of these reactions was monitored with NMR (¹H, ¹³C and ¹⁵N) and UV-Vis spectroscopy as well as square wave stripping voltammetry. The kinetics of the substitution reactions between the above-mentioned complexes with thione ligands were studied in aqueous solutions containing 30 mM KCl, which is used to suppress hydrolysis of the chloride complex. The reactions were followed under pseudo first-order conditions as a function of ligand concentration, pH and temperature in the range of 15-37 °C. The activation parameters (ΔH^\ddagger , ΔS^\ddagger) were calculated from Eyring plot and the negative values of ΔS^\ddagger lend support for an associative mechanism. The kinetic data also indicate a relatively higher reactivity of [Au(*cis*-DACH)Cl₂]Cl than [Au(*cis*-DACH)₂]Cl₃ towards the thiones.

The interaction of [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ complexes [where *cis*-DACH: is *cis*-1,2-diaminocyclohexane] with enriched (¹³C, ¹⁵N) KCN were carried out in CD₃OD and D₂O, respectively. The reaction pathways of these complexes were studied by ¹H, ¹³C, ¹⁵N NMR, UV spectrophotometry and electrochemistry. The kinetic data of the reaction of cyanide ion with [Au(*cis*-DACH)₂]Cl₃ are found to be $k = 18$

$\text{M}^{-1}\text{s}^{-1}$, $\Delta H^\ddagger = 11 \text{ kJmol}^{-1}$, $\Delta S^\ddagger = -185 \text{ JK}^{-1}\text{mol}^{-1}$, and $E_a = 13 \text{ kJ mol}^{-1}$ with SWV peak +1.35 V, whereas the kinetic data for the reaction of cyanide ion with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ are found to be $k = 148 \text{ M}^{-1}\text{s}^{-1}$, $\Delta H^\ddagger = 39 \text{ kJmol}^{-1}$, $\Delta S^\ddagger = -80 \text{ JK}^{-1}\text{mol}^{-1}$, and $E_a = 42 \text{ kJmol}^{-1}$ along with SWV peak +0.82 V, indicating the much higher reactivity of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ toward cyanide ligand than $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$. The interaction of these complexes with potassium cyanide resulted in an unstable $[\text{Au}(\text{}^{13}\text{CN})_4]^-$ specie, which readily underwent reductive elimination reaction to generate $[\text{Au}(\text{}^{13}\text{CN})_2]^-$ and cyanogen (NCCN).

Kinetic measurements revealed the rate constants of the interaction between $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with Tu and DIAZ are 49.50; 121.70 and 24.31; 46.65 $\text{M}^{-1}\text{s}^{-1}$, respectively, at 288 K and 310 K. Similarly, the rate constants for $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu and DIAZ are found to be 41.88; 64.86 and 21.68; 40.89 $\text{M}^{-1}\text{s}^{-1}$, respectively at 288 K and 310 K. $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ reacted faster towards thione ligands than $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ complex; also Tu reacted faster than DIAZ towards these complexes. The negative values of ΔS^\ddagger for these reactions lend support for an associative mechanism.

عنوان الرسالة:

اصطناع وتقييم تضاد السرطان لمعقدات الذهب(1+) المشتقة من لاقطات الفوسفينات مع

كاربومات ثنائية الكبريت ودراسة تفاعلات معقدات الذهب(3+) المشتقة من لاقطة

1,2-ثنائي أمين الهكسان الحلقي مع بعض الجزيئات الحيوية

التخصص:

علوم الكيمياء

تاريخ الدرجة العلمية:

مايو 2016

التقدم المتزايد حديثا في مجال صناعة أدوية السرطان مع اكتشاف معقدات الذهب(1+) أدى الى اختراع معقدات ذهب(1+) جديدة ذات تركيبة خطية حول أيون الذهب المركزي. حضرت مجموعات متسلسلة من معقدات الذهب(1+) (2-17)، (18-22)، (23-26)، (27-30) و(31-34) مشتقة من لاقطات ثنائي ميثيل ثنائي كبريت-الكاربومات وثنائي إيثيل ثنائي كبريت-الكاربومات وثنائي بنزيل ثنائي كبريت-الكاربومات بالإضافة الي لاقطات فوسفينات مختلفة. هذه المعقدات أنفة الذكر تم تحضيرها من تفاعل مركب الذهب(1+) المشتق من كلوريد وثلاثي ألكيل/أريل الفوسفين مع لاقطات الكاربومات المذكورة سابقا. المركب الأولي ثلاثي ألكيل/أريل فوسفين كلوريد الذهب(1+) حضر من تفاعل مركب ثنائي ميثيل كبريتيد كلوريد الذهب(1+) مع مختلف لاقطات أحادية وثنائية الفوسفين.

بالإضافة الي هذه المعقدات تم تحضير معقدات أخرى وهي فوسفينات الذهب(1+) (35-37)، كاربينات سيلونات الذهب(1+) (39-50)، ثيونات الذهب(1+) (51-55) وكاربينات الذهب(1+) المرتبطة بفوسفينات احادية وثنائية (56-65). درست خصائص هذه المعقدات بواسطة مطيافية الأشعة تحت الحمراء والرنين النووي المغنطيسي لأنوية الهيدروجين والكربون والفسفور والسيلينيوم بالإضافة الي تحليل العناصر ومطيافية حيود الأشعة السينية للبلورات. المعقدات بالارقام 27, 39, 44, 46, 48, 49, 54, 55, 56, 61, 63 و65 درست خصائصها بواسطة مطيافية حيود الأشعة السينية وقد أظهرت تركيبة هندسية خطية حول أيون الذهب(1+) المركزي.

أجريت دراسة فاعلية هذه المعقدات مختبريا علي ثلاثة أنواع من خلايا السرطان المصنعة وهي سرطان الرئة والقولون وعنق الرحم. أظهرت المعقدات بالارقام 20-22 فاعلية قوية جدا ضد خلية سرطان الرئة أكثر من تلك التي أعطيت بواسطة معقد سيس بلاتين(2+) كعلاج قياسي لمعظم أنواع السرطانات. كذلك المعقد 48 أظهر فاعلية قوية

ضد خلية سرطان القولون أكثر من معقد السيس بلاتين(2+). بينما المعقدات الأخرى أعطت فاعلية أقل من تلك التي وجدت لمعقد السيس بلاتين(2+) ضد خلايا سرطان الرئة والقولون وعنق الرحم.

من جهة أخرى حضرت معقدات الذهب(3+) المشتقة من 2,1-ثنائي أمين الهكسان الحلقي ودرست تفاعلاتها مع لاقطات السيانييد والثيوبيوريا و3,1-ثنائي ازانين-2-ثيون بواسطة مطيافية الضوء المرئي-الأشعة فوق البنفسجية والرنين النووي المغناطيسي لأنوية الهيدروجين والكربون والنيتروجين بالإضافة الي فولتية تعرية الموجة المربعة.

درست حركية تفاعلات الاستبدال لمعقدات الذهب(3+) مع اللاقطات الأنفة الذكر، عن طريق الرتبة الأولى الكاذبة في درجات حرارة تتراوح بين 15-37 درجة مئوية في محاليلها المائية، والتي احتوت علي كلوريد البوتاسيوم بتركيز 30 ملليمولار لمنع ايونات كلوريد هذه المعقدات من التحلل.

حسبت معدلات سرعة التفاعل بالإضافة الي حركية التنشيط لطاقات المحتوى الحراري والانتروبيا لهذه المعقدات باستخدام معادلة ارينج. اوضحت الدراسة بان معقدات الذهب(3+) المشتقة من 2,1-ثنائي أمين الهكسان الحلقي المرتبطة بأيونات الكلوريد أسرع تفاعلا تجاه لاقطات السيانييد والثيوبيوريا و3,1-ثنائي ازانين-2-ثيون من تلك التي لا تحتوي علي الكلوريد وكذلك السيانييد اسرع من الثيوبيوريا و3,1-ثنائي ازانين-2-ثيون. كما اوضحت الدراسة ان معقدات الذهب(3+) غير مستقرة حينما تختزل الى معقدات الذهب(1+) في وجود هذه اللاقطات.

CHAPTER 1

INTRODUCTION

1.1. Gold(III) complexes

Gold was discovered as shining yellow chunks, its symbol derived from Latin name *Aurum*. In early civilizations, humans almost spontaneously attribute a high value to gold associating it with power of beauty. In the ancient time 2500 BC, Chinese and Arab have used gold in medicine. Gold possesses special characteristic features that make it unique, such as high chemical and thermal stability, mechanical softness and high electrical conductivity. Gold(III) has electronic configuration d^8 ($[\text{Xe}]4f^{14}5d^8$) and forms diamagnetic four coordinate $16e^-$ species with predominantly square-planar geometry analogue to Pt(II) complexes. Five coordinate gold(III) complexes are rare [1-2].

The unexpected disclosure of cisplatin by Rosenberg in 1965 proclaimed another region of anticancer medication research on metal-based medication [3]. Cisplatin has been a standout amongst the best chemotherapies in the most recent 30 years, and has been utilized to treat various sorts of tumor diseases. In spite of having great usefulness as a chemotherapeutic, cisplatin has downsides; tumors regularly create imperviousness to the medication, and patients routinely encounter serious symptoms over the span of treatment [4]. Subsequently, scientists are consistently searching for remedial options that may

enhance these constraints. Common problems include cumulative toxicities of nephrotoxicity and cytotoxicity [5–8]. Notwithstanding the genuine symptoms, the remedial adequacy is additionally constrained by regular or treatment-impelled resistance tumor cells. These drawbacks have given the inspiration to select chemotherapeutic procedures. To stay away from the issue of medication resistance in cisplatin, gold(III)-based compounds have been outlined as a potential distinct option for cisplatin [9–13].

Gold(III) derivatives have significantly pulled in researcher's consideration in the most recent decade for their exceptional cytotoxic activities. It is a metal ion which normally has a four-coordinate, square-planar geometry and anticipated to emulate the structure and electronic properties of platinum(II). Late studies have demonstrated that few gold(III) compounds are exceptionally cytotoxic against various tumor cells [10, 14–16], including some which are active even against the cisplatin-resistance cell lines [17–19]. A few lines of confirmation propose that gold (III) complexes produce their anti-proliferative impacts through innovative and nonconventional modes of activity. Case in point, the speculation that their biological impacts are mediated by an antimitochondrial mechanism rather than by direct DNA damage, as it is the situation for cisplatin and its analogs, has increased much credit amid the most recent couple of decades [12].

The stringent relationship to Pt(II) complexes makes Au(III) compounds great possibility for improvement and testing as anticancer medications, despite the fact that the generally high kinetic lability and the normally high redox possibilities have to a great extent ruined such investigations. These drawbacks can be dodged by shaping gold(III) derivatives with one or more multi-dentate nitrogen ligands to upgrade the strength and stability of gold(III) complexes [20–22]. Some recent studies point out that novel gold(III) complexes show

good antitumor properties both *in-vitro* and *in vivo*, have bringing new enthusiasm up in this research field [23–25].

A number of structurally analogues of cisplatin [26] have been tested, later utilized in clinical practice [27], one of these is trans-1,2-diaminocyclohexane dichloridoplatinum(II) (DACH) [28]. Since the molecule is chiral, the pertinence of stereochemistry has been addressed by researchers [29]. The ligand DACH has three isomeric structures: (1R, 2R-DACH) (*trans*-DACH), (1S, 2S-DACH) (*trans*-DACH) and (1R,2S-DACH) (*cis*-DACH). Disregarding conflicting perspectives [30 –34], the agreement is that the (R, R) isomer is more active than the (S,S) isomer [35-36], in spite of the fact that activity has additionally been shown for the (R, S) isomer [37]. As the stereochemistry of the complexes, the DACH platinum compounds of Pt(1R,2R-DACH) and Pt(1S,2S-DACH) have a higher antitumor activity than Pt(1R,2S-DACH) complex [38–40].

1.2 Gold(I) complexes

Gold(I) has d^{10} electron configuration which is divided into three distinct classes of co-ordination environments: linear two coordination, so far the most important co-ordination environment along with trigonal three-coordination and tetrahedral four-coordination.

Gold(I) is a soft cation with susceptibility for soft ligands such as: cyanide, thiolate, halide (e.g. iodide), and phosphine to form stable species of AuX_2^- , and AuL_2^+ , respectively [41–43]. During the last two decades, a large variety of gold(I) and gold(III) compounds have been reported to possess anti-proliferative properties *in vitro* against several human tumor cell lines, qualifying them as excellent candidates for further pharmacological evaluation.

The recent literature shows a high number of papers reporting gold(I) phosphine complexes with sulphur ligands with application in catalysis, biological activities, luminescence, and the medical field. Moreover, the aurophilic interaction is well known in gold compounds containing P-, S-, and N- ligands [44–48], Fortman et al. studied thermodynamics of ligand exchange reactions in [(tth)AuCl] (tth= tetrahydrothiophene) with a series of tertiary phosphines and phosphites. They found that P—Au bond formed to be largely dependent on electronics parameters of phosphorus donor, whereas steric of ligand seems to play only a minor role in affecting enthalpy and BDE (bond disassociation energy). The phosphite ligands bind more weakly to Au centre than phosphine [49].

Gold(I) can be oxidized to gold(III) in vivo e.g. by myeloperoxidase system in white cells, that may be responsible for side-effects of gold(I) drugs [50]. On the other hand, gold(I) predominates the biochemistry of gold compounds, which is stabilized via π -acceptor ligands.

Auranofin is the first gold(I) phosphine lipophilic complex utilized into clinical practice for the treatment of rheumatoid arthritis. Also some of mixed ligands phosphine and thiolate gold(I) complexes have been tremendously shown to induce cell death, with varying characteristics depending on the cell type such as: solganol, myocrisin, sanocrysin, and allocrysin (Scheme 1).

Scheme 1: Some gold(I) complexes are used in rheumatic arthritis treatment.

These complexes and other gold(I) compounds including phosphine ligands such as GoPl (Scheme 2) have been reported to show bioactivities and anticancer activity [43, 51-52].

Scheme 2: Gold(I) phosphine anticancer drug (GoPl)

Gold(I) N-heterocyclic carbene (NHC) complexes were obtained in good yields from the corresponding silver complexes by treatment with $[\text{AuCl}(\text{PPh}_3)]$. These complexes have been characterized by ^1H , ^{13}C -NMR, IR spectroscopy and elemental analysis. Au-NHC complexes were evaluated for their in vitro antimicrobial activity against a variety of Gram-positive and Gram-negative bacteria and fungal species [53].

A series of gold(I) phosphine complexes containing naphtha-imide ligand have been shown promising properties of anticancer drugs development, along with strong

anti-proliferative effects in MCF-7 breast cancer cells and HT-29 colon carcinoma cells [54].

In this thesis, I would like to explore the nature of bonding in Au(III) *cis*-DACH type complexes and to study their stability, when exposed to cyanide, thiones. Cyanide occurs naturally and blood of smokers contains high amount of SCN^- . Myeloperoxidase (MPO) converts SCN^- to cyanide. ^1H , ^{13}C , and ^{15}N solution NMR were used to study these interactions. In addition, different types of $[(\text{R}_3\text{P-Au-S}_2\text{CNR})]$, gold(I)_carbene with selones, gold(I)_ter-t-butylphosine with thione, and gold(I)_carbene with phosphine complexes were synthesized, and then were characterize by using ^1H , ^{13}C , ^{31}P solution and solid NMR.

1.3 RESEARCH OBJECTIVES

1. Preparation of the two complexes, $[\textit{cis}\text{-1,2-(DACH)AuCl}_2]\text{Cl}$ and $[\textit{cis}\text{-1,2-(DACH)}_2\text{Au}]\text{Cl}_3$.
2. Study of interactions of the complexes prepared in objective 1 with thiones such as IMT, DIAZ, and DIAP along with thiourea and cyanide using UV spectroscopy, ^1H NMR, ^{13}C NMR, and ^{15}N NMR.
3. Study of interactions of these complexes with labeled nucleobases: Guanine (8- ^{13}C , 7, 9 $^{15}\text{N}_2$), Adenine (8- ^{13}C , 6-amino and 1, 9 $^{15}\text{N}_2$), Cytosine (2,4- $^{13}\text{C}_2$, $^{15}\text{N}_3$) and Uracil (1,3 $^{15}\text{N}_2$) using UV spectroscopy, ^1H NMR, ^{13}C NMR, and ^{15}N NMR methods.

4. Synthesis of complexes of the type $[R_3P-Au-PR_3]^+$ and $[R_3P-Au-S_2CNR_2]$, where $PR_3 = (1R,2R)$ -2-(diphenylphosphino)-1-aminocyclohexane, (R)-1-(diphenylphosphino)-2-amino-3,3-dimethylbutamine, (S)-1-(diphenylphosphino)-2-amino-3,3-dimethylbutane, (1R,2R)-2-(diphenylphosphino)-2,3-dihydro-1H-inden-1-amine, (1R,2R)-2-(diphenylphosphino)-1,2-diphenylethylamine, 2-(diphenylphosphino)ethylamine, (R)-1-[(2-diphenylphosphino)phenyl]ethylamine, (S)-1-[(2-diphenylphosphino)phenyl]ethylamine, (R)-[(2-diphenylphosphino)phenyl]-1-phenylethylamine, (3-diphenylphosphino)propylamine, 2-(D-i-propylphosphino)ethylamine, and 3-(D-i-propylphosphino)propylamine and $NR_2CS_2^- =$ dimethyldithiocarbamate (DMTC), diethyldithiocarbamate (DETC), and dibenzylthiocarbamate (DBTC).
5. Characterization of gold(I) phosphine complexes using 1H , ^{13}C , ^{31}P NMR, IR, elemental analysis, and single crystal X-ray.
6. Study of their cytotoxic activity against A549 (human lung cancer), MCF7 (human breast cancer), and HCT15 (human colon cancer) cell lines.

CHAPTER 2

LITERATURE REVIEW

2.1. Gold(III) complexes

Since early 1990s, the chemistry of gold has been a well-established area of research. The metal and its complexes have special characteristic features that make them suitable for several research fields. For instance, a huge number of these complexes have antitumor action with positive results [55, 56]. Recently, using various Au(III) complexes with novel functionality has elicited more interest due to their distinct physical and chemical properties, stability under physiological conditions, and outstanding cytotoxic effects [57,58]. Cis-diamminedichloridoplatinum(II) (cisplatin) is one of the most widely used anticancer drugs today. However, platinum compounds possessing the 1,2-diaminocyclohexane (DACH) carrier ligand offer advantages over cisplatin with regard to bioavailability, activity and decreased renal toxicity [59]. Furthermore, success of oxaliplatin, (1R,2R-DACH)PtC₂O₄ complex, raised considerable research interest over the past three decades in platinum–DACH complexes [60].

2.1.1. Complexes formed from (C, N) donor ligands

Bugarčić et. al. [61] recently have studied the kinetics of the substitution reactions of gold(III) compounds bearing 3-azapentane-1,5-diamine, 2,2',6',2''-terpyridine, 2,2'-bipyridine and 1,2-diaminocyclohexaneligands associated with biologically applicable ligands, for example, L-histidine (L-His), inosine (Ino), inosine-5'-monophosphate (5'-IMP) and guanosine-5'-monophosphate (5'-GMP). Their outcomes demonstrated that the $[\text{Au}(\text{terpyridine})\text{Cl}]^{2+}$ complex is the most reactive one, which was affirmed by (DFT) computations [61]. The nucleophiles reactivity order are: L-His > 5'-GMP > 5'-IMP > Ino.

As per the deliberate activation parameters, all studied reactions affiliated an associative substitution mechanism. The outcomes show strong association between the reactivity of these complexes toward biological pertinent ligands and their chemical and electronic characteristics. Hence, the binding of gold(III) compounds to 5'-GMP, constituent of DNA, is exceptionally compelling since this connection is thought to be in charge of their anticancer activity.

Over the past several years, significant effort has been devoted to study the antitumor activity of platinum-DACH complexes, whereas, gold-DACH complexes [62] have generally little consideration despite the fact that gold(III) has a genuinely rich biological nature. For instance, it has redox activity, can be facilitated by amino acids and proteins [63]. As on account of cisplatin, the anticancer activity of platinum-DACH is associated by some toxicity. The rise of resistance and low water solubility that can influence the pharmacokinetics are extra components that should be enhanced in the mission for more successful analogues [64].

Promising results were obtained with a class of gold(III) compounds with 2-(dimethylamino)methylphenyl ligand synthesized in such an approach to settle gold in its +3 oxidation state. These compounds showed cytotoxic impacts against a few human tumor cell lines, tantamount to, or more noteworthy than cis-platin [65].

In recent literature Messori et al. brought up the in vitro test of a series of gold(III) compounds, such as $[\text{Au}(\text{en})_2]\text{Cl}_3$ against the A2780 ovarian malignancy cell line and a cisplatin safe variation [10, 65]. A number of other gold(III) compounds have been prepared and their cytotoxicity has been assessed. Calamai et al. studied gold(III) compounds containing no less than two gold-chloride bonds in cis-position [66, 67].

Arsenijevic et al [68] studied the kinetics of the reaction of $[\text{Au}(\text{en})\text{Cl}_2]\text{Cl}$, $[\text{Au}(\text{bipy})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{DACH})\text{Cl}_2]\text{Cl}$ with 5'-GMP. They observed the spectral changes upon mixing of the complex with the 5'-GMP in λ_{max} in the range (280–350 nm). All kinetics measurements were performed under pseudo-first order conditions. The activation parameters suggest an associative mechanism. They measured their reactions at three different temperatures and reported the rate constants and activation parameters.

In biological systems, the imidazole group of histidine is frequently found in combination with copper ions, but also with nickel and zinc ions whereas the cobalt ion, in vitamin B₁₂, is coordinated to the benzimidazole group [69, 70]. In the blue copper protein, the Cu(II) is ligated in a distorted-tetrahedral arrangement of two histidine nitrogens, a cysteine thiolate sulfur and a methionine thioether sulfur [71]. For the modeling of this active site, imidazole- and thioether containing ligands are relevant.

Imidazole as shown below is a planar 5-membered aromatic molecule [72]. The electrons in the unhybridized p-orbital of N1 form part of the aromatic sextet. The all-electron computation for the imidazole [73] molecule was reported previously, and the net charges at the nitrogen atoms obtained from ab initio calculations are calculated.

Scheme 3. Basic imidazole structure (both N1 and N3 has one lone pair each).

The nitrogen atoms in imidazole are in two different environments. The N1 electrons are not available for bonding, since the aromaticity of the imidazole molecule will be compromised, unless this nitrogen deprotonates and has an available pair of electrons. The N3 nitrogen displays fractionally negative σ and π electron charges, indicating that it is a modest σ -donor and a weak π -acceptor when involved in bonding. Therefore, the imidazole molecule presents a single energetically favorable coordination site for a metal ion, namely the unshared electron pair on N3.

A metal ion can bind at N3, thereby forming a metal ion complex containing a neutral imidazole. In fact, there are extensive studies of biological systems with the imidazole core, especially with N-alkylated derivatives, and these models display the coordination of the N3 nitrogen to the metal ions [69, 70, 73-74]. However, the neutral imidazole can be deprotonated at N1 in strongly basic solutions.

Megumu et al. [75] have already studied the interactions of imidazole with Cd^{2+} in solution. Barbarossou et al. [76] have studied the interaction of the mononucleotides guanosine-5'-monophosphate ($5'\text{-GMP}^{2-}$) and inosine-5'-monophosphate ($5'\text{-IMP}^{2-}$) with Na^+ , Ba^{2+} , and Cd^{2+} by ^{15}N and ^{113}Cd CP MAS NMR spectra in the solid state at natural abundance. The ^{15}N CP MAS NMR spectrum of $\text{Cd}(5'\text{-GMP})\cdot 5\text{H}_2\text{O}$ shows sharp single resonances for all the purine nitrogens in agreement with the X-ray structure, which demonstrates the presence of one nucleotide and one metal ion per crystal unit [77]. The X-ray structure is typical for transition and heavy metal complexes with a 1:1 ratio of metal to guanosine-5'-monophosphate monomeric structure with the general formula $[\text{M}(5'\text{-GMP})(\text{H}_2\text{O})_5]\cdot n\text{H}_2\text{O}$. The common features of this type of structure are the M-N (7) metal bonding and three intramolecular hydrogen bonds; one between a water molecule and O(6) and two between water molecules and phosphate oxygens. The N(7) resonance absorption in Cd^{2+} complex is strongly shielded by -29.6 and -31.9 ppm compared to that of the Na^+ and Ba^{2+} complexes, respectively. This demonstrates significantly different binding modes to N(7), although X-ray structural data have been interpreted in terms of direct metal ion-N(7) interaction for Na^+ , Ba^{2+} , and Cd^{2+} complexes [78-79]. Unambiguous demonstration of a direct Cd-N coordination bond is provided by the ^{113}Cd CP MAS NMR spectrum, which indicates the presence of an asymmetric 1:1:1 triplet due to (^{113}Cd , ^{14}N) indirect and residual dipolar spin-spin interactions [80–82].

2.1.2 Complexes formed from (N, S) donor ligands

Thiolate complexes are of great importance from a bioinorganic point of view, mainly due to the presence of thiolate donors in the coordination sphere of many metal ions in very diverse metalloproteins [83, 84].

Complexes of heterocyclic thiones such as imidazolidine-2-thione (Imt), diazinane-2-thione (Diaz) and their derivatives with transition metals are of interest in bioinorganic chemistry because of the search for simple model compounds for metal proteins [84–86]. In view of this, copper(I) [89], silver(I) [88, 89], gold(I) [90–92], mercury(II) [93, 94] and cadmium(II) [95] complexes with thiones have been widely studied in recent years. the coordination chemistry of $>C=S$ ligands with d^{10} metal ions have been investigated in an attempt to assess their mode of binding and to study their physical properties [96–97]. In biological systems, the imidazole group of histidine is frequently found in combination with copper ions, but also with nickel and zinc ions whereas the cobalt ion in vitamin B₁₂ is coordinated to the benzimidazole group [69, 70]. In the blue copper protein, the Cu(II) is ligated, in a distorted-tetrahedral arrangement to two histidine nitrogens, a cysteine thiolate sulfur and a methionine thioether sulfur [96]. For the modeling of this active site, imidazole- and thioether containing ligands are relevant. Mononuclear Au(III) compounds of the peptides H-His-Met-OH (D) and H-Gly-Gly-Met-OH (T) were structurally characterized by IR, MS and NMR [86]. In Au(III) complexes with dipeptides, Au(III) is bonded to S of imidazole, N of methionine and histidine ligands shaping macrochelate rings [98].

The dithiocarbamate gold(III) compounds have additionally been analyzed lately [99]. Dimethyl dithiocarbamate (DMDT) which forms [(DMDT)AuX₂] demonstrate more cytotoxic action than cisplatin even toward human tumor cell lines naturally impervious to cisplatin itself.

Dinger and Henderson [100] have additionally shown the potential pharmacological action of gold(III) compounds. They portrayed the synthesis of cycloaurated N,N-dimethyl-

benzylamine compounds, these compounds showed better cytotoxic action in vitro. These compounds were assessed against the P388 leukemia cell line, and subsequently their potential activity against human tumors requires further examination.

El-Maythality et al. monitored the interaction of auricyanide $[\text{Au}(\text{CN})_4]^-$ with biologically important thiols, thioether and selenoether using ^1H and ^{13}C NMR and UV spectroscopy. These ligands include L-cysteine, glutathione, captopril, L-methionine and DL-seleno-methionine. They pointed out L-cysteine reaction mechanism with $[\text{Au}(\text{CN})_4]^-$ was found to be dependent on reactants mole ratio. While L-methionine was completely inert toward auricyanide, DL-Se-methionine showed some reactivity with $[\text{Au}(\text{CN})_4]^-$ after raising solution pH to 12 that facilitated cyanide exchange [101].

Kouroulis et al. showed that the reaction of tetrachloroauric(III) with the thioamides ligands leads to the desulfuration of these ligands. They demonstrated that the reaction of HAuCl_4 with 2-mercapto-nicotinic acid, leads to 2-sulfonate-nicotinine with the synchronous oxidation of the sulfur molecule. While the reactions of the gold(I) complex $[\text{Au}(\text{Ph}_3\text{P})\text{Cl}]$ (Ph_3P = triphenylphosphine) with the thioamides, 2-mercapto- thiazolidine (mtzdH), 2-mercapto-benzothiazole (mbztH) and 5-chloro-2-mercapto- benzothiazole (ClmbztH) in the presence of potassium hydroxide brought about the arrangement of the gold(I) complexes without ligand desulfuration and were investigated by spectroscopic methods such as FT-IR, far-FT-IR, ^1H -NMR and X-ray crystallography. These complexes were tested in vitro for their cytotoxicity against leiomyosarcoma cells [102].

Scheme 4: Thioamide ligands.

Glišić et al. used spectroscopic (^1H -NMR and UV-vis) and electrochemical (CV) techniques to study the interaction of Gly-Met dipeptide with $[\text{Au}(\text{en})\text{Cl}_2]^+$ complex resulting Gly-Met sulfoxide, formed by the oxidation of methionine residue with $[\text{Au}(\text{en})\text{Cl}_2]^+$. The formation of Gly-Met sulfoxide proceeds through two steps including the monodentate coordination of thioether sulfur atom of methionine residue and release of en ligand from Au(III). In addition, the obtained kinetic data showed that oxidation of methionine residue in Gly-Met was 200 times slower in comparison to the same process with $[\text{AuCl}_4]^-$ complex. The variation in the oxidation rate of Gly-Met between these two complexes was attributed to the presence of chelated ethylenediamine ligand in $[\text{Au}(\text{en})\text{Cl}_2]^+$ [103].

Scheme 5: Oxidation of methionine residue in Gly-Met dipeptide in the presence of $[\text{Au}(\text{en})\text{Cl}_2]^+$ [103].

Chi et al. prepared a series of new potential anticancer Au(III) complexes such as $[(\text{PipDTC})\text{AuCl}_2]$ with macro-cyclic amine-based dithiocarbamate ligands. These complexes were characterized by elemental analysis, IR, UV, NMR, conductivity measurements and X-ray diffraction analysis. They have selective cytotoxic effects against a panel of human cancer cells lines. All these complexes show higher cytotoxicity than *cisplatin* against all examined cell lines. The nature of cyclic amine and the number of metal centers have important impacts on cytotoxicity of these complexes [104].

In 2012, a series of new gold(III)-dithiocarbamate (dtc) complexes of oligopeptides as promising potential anticancer drugs were synthesized to obtain metal peptidomimetics compounds. In vitro cytotoxicity studies pointed out some of them to be the most effective toward the four evaluated human tumor cell lines (PC3, 2008, C13, and L540), for which the IC_{50} values were lower than *cisplatin* [105].

In 2014, M. D. Đurović et al. studied the effect of tridentate, nitrogen donor ligands on stability of gold(III) complexes under physiochemical conditions. They have monitored the interaction of $[Au(terpy)Cl]^{2+}$ (terpy = 2,2':6, 2'' terpyridine), $[Au(bpma)Cl]^{2+}$ (bpma = bis(pyridyl-methyl)amine), $[Au(dien)Cl]^{2+}$ (dien=diethylenetriamine) and $[AuCl_4]^-$ with biological thiols, L-cysteine (L-Cys), glutathione (GSH) and L-methionine (L-Met) using UV-Vis and 1H NMR spectroscopy techniques, cyclic voltammetry and ESI-MS. The obtained second-order rate constants were determined at different initial concentrations of reactants, chloride ions, pH and constant ionic strength [106].

2.2 Gold(I) Complexes

2.2.1 Complexes formed from (P, S, Se) donor ligands

Dithiocarbamates are versatile ligands used in a wide range of application such as medicine, industry, agriculture and catalysis. Recently, gold(I) phosphine complexes have exhibited promising results as novel antitumor drugs against a wide variety of different malignancies.

Scheffler et al. reported a series of chlorido gold(I) phosphine complexes ($Cl-Au-PR_3$) R= Me, Et, tert-But, Ph). They showed the influence of R group on cytotoxicity, cellular and

nuclear uptake in HT-29 colon carcinoma and MCF-7 breast cancer cells. These complexes showed significant cytotoxicity results [107]. Four-coordinate gold(I) complexes, containing mono-phosphine ligands, these complexes showed strongly luminescence in liquid nitrogen and weakly at room temperature in addition to high cytotoxicity against a panel of cancer cell lines [108].

Gold(I) thiolate complexes are used extensively in medicine. For instance, gold(I) thiosemicarbazone complexes exhibited high efficacy as antimalarial agent [109]. In addition, a series of gold(I) complexes with mixed phosphine and dithiocarbamate ligands have been synthesized. The stability of these complexes depends on the nature of phosphine used. Bis(phenylphosphino) ligands, with alkyls higher than ethyl give stable gold(I) complexes in solution (Scheme 6). All these complexes showed promising anticancer activity against HeLa cancer cell lines [110].

Scheme 6: Gold(I) with monophosphophine and dithiocarbamate complexes (1-3), gold(I) with (bis-phosphino)alkyl and dithiocarbamate complexes(4-12)[110].

Jamaludin et al. [111] reported three $R_3PAu[S_2CN(ipr)CH_2CH_2OH]$ complexes, where R is Ph(1), Cy(2) and Et (3). They showed influence of substituted phosphine on in vitro cytotoxic activity against breast cancer cell line and death of cell pathways. They found that complex (1) is the most efficient even more than cisplatin and follows apoptotic pathway for cell death, whereas for complexes 2 and 3, the cell death is caused by necrosis (Figure 1).

Figure 2.1. Signaling pathway of apoptosis induced by 1, 2 and 3. This diagram collates and summarizes the results of the PCR array analysis, caspase activity study, DNA fragmentation and ROS production measurements [111].

Recently, phosphinogold(I) organoselenium complexes have emerged as a new area in drugs delivery and medicinal applications due to the facts that selenoproteins play important role in the metabolism and antioxidant [112–114]. A series of organoselenogold(I) complexes (Scheme 7) were reported to have antimalarial activity. These complexes showed moderate activity compared to chloroquine [115].

Scheme 7: Mono- and binuclear gold(I)phosphine complexes containing monoanionic seleno- and thiosemicarbazone ligands [115].

Abdulah et al. reviewed important biological roles of selenium in cancer prevention worldwide. They reported that the first clinical trials with Se to induce DNA damage and repair were performed in China [116].

Al-Maythalony et al. reported Hg(SeCN)₂ and Cd(SeCN)₂ complexes with histidine and glycine, they studied their anti-bacterial activities and they found that histidine ligates more strongly than glycine. Cd(II) complexes have exhibited significant antimicrobial activity [117]. Isab et al. demonstrated that Me₃PAu⁺ moiety coordinates more strongly to Se containing ligands than Et₃PAu⁺ and Ph₃PAu⁺ moieties, therefore, Me₃PAu⁺ with selenium ligands lend to less side effects as anticancer agents [118].

Gold complexes bearing N-Heterocyclic carbene (NHC) ligands have been extensively used in the fields of catalysis [119], anticancer [120] and antimicrobial [121]. Water

soluble NHC complexes with coinage metals (Cu, Ag, Au) have been prepared and their biological activity evaluated against A549 lung cancer, HCT-15 colon cell line and selenocystiene TrxR (Scheme 8). Au and Ag complexes were found more active than Cu complexes [122].

2.2.2 Complexes from (P, C, N) donor ligands

Scheme 8. Reaction scheme of complexes from **2** to **7** [123].

Messori et al. synthesized a series of Au(I)-NHC compounds. They further functionalized these compounds as useful active esters to enhance their cytotoxicity and selectivity towards human ovarian cancer A2780 cells and HEK-293T cells (Scheme 9). The functionalized compounds exposed promising anti-proliferate properties and significant selectivity to these cells (Scheme 10) [123].

Scheme 9. Synthesis of different Au(I)-NHC compounds bearing pentafluorophenol ester moiety.

Scheme 10. Synthesis of different Au(I)-NHC compounds through reaction of activated ester moiety.

Two novel Au(I)-NHC complexes with high solubility in physiological media have been prepared (Scheme 11). These complexes completely overcome the resistance of cisplatin against A2780 cell line, and their activity against three types of proteins were observed [123].

Scheme 11. (a) Synthesis of compound 1 (b) Synthesis of compound 2.

The high *in vitro* and *in vivo* proficiency binuclear gold(I) complex (**1-PF₆**) with mixed diphosphine and bis-(NHC) ligands, with selective thiol reactivity has been prepared (Figure 2.2). Bis-(N-heterocyclic carbene) to enhance thiol stability and biphosphine to tune thiol reactivity. The stability of this complex allows selective inhibition of thioredoxin reductase (TrxR) without reacting with blood thiol. *In vitro* studies were performed against cancer stem cells and *in vivo* against tumor *HeLa xenograft* in mice and mouse *B16- F10 melanoma* [124].

Figure 2.2. Chemical structures of **1–5** complexes and auranofin.

CHAPTER 3

SYNTHESIS, ANTI-CANCER EVALAUTION OF NEW MIXED-LIGAND GOLD(I) COMPLEXES WITH DITHIOCARBAMATES AND PHOSPHINES

3.1 EXPERIMENTAL SECTION

3.1.1 Materials and Instrumentation

All solvents are analytical grade used without further purification. (1R, 2R)-N, N-Bis[2-(diphenylphosphino)benzyl]cyclohexane 1,2-diamine, bis[2-(dicyclopophosphino)ethyl]amine, bis[(2-diphenylphosphino)ethyl]ammonium chloride, (1S, 2S)-N, N-Bis[2-(diphenylphosphino)benzyl]cyclohexane 1,2-diamine, 2-(diphenylphosphino) ethylamine, (1R,2R)-2-(diphenylphosphino)-2,3-dihydro-1H-inden-1-amine, (R₁, R₂)-2-(diphenylphosphino)-1-aminocyclohexane, triphenylphosphine,

tri(o-methoxyphenyl)phosphine and 2-(di-isopropylphosphino)ethylamine, bis(2-cyanoethyl)phenyl phosphine were purchased from Stream Chemicals Inc. (Newburyport, Massachusetts, United States). Dimethylsulfide, sodium tetrachloroaurate(III), ethanol, diethyl ether, dichloromethane from Fluka AG (St. Gallen, Switzerland).

^1H and ^{13}C NMR spectra were recorded on a JEOL-LA 500 NMR spectrophotometer, operating at 500.0 and 125.65 MHz, respectively, corresponding to a magnetic field of 11.74 T. The spectral conditions included 32 k data points, a 3.2 s acquisition time, and a 5.75 μs pulse width. ^{13}C NMR spectra were obtained with ^1H broadband decoupling and following spectral conditions: 32 k data points, a 1 s acquisition time, a 2.5 s pulse delay, and a 5.12 μs pulse width. ^{31}P NMR spectra were obtained at 200.0 MHz, with phosphoric acid as an external standard. All spectra were recorded at 297 K in CDCl_3 using tetramethylsilane (TMS) as an internal standard.

Elemental analyses were obtained on Perkin Elmer Series 11 (CHNS/O), Analyzer 2400. The solid state FT-IR spectra of the free ligands and their gold(I) complexes were recorded on a Perkin Elmer FT-IR 180 spectrophotometer, using KBr pellets over the range 4000-400 cm^{-1} . Single crystal X-ray crystallography.

3.2 Synthesis of binuclear Gold(I) complexes with mixed bis-phosphine and dithiocarbamate ligands

3.2.1 $[\text{Au}_2((1\text{R},2\text{R})\text{-N,N-Bis[2-(diphenylphosphino)benzyl]cyclohexane-1,2-diamine)}\text{Cl}_2]$ with dialkyl and diaryldithiocarbamate ligands (1-5)

DMDTC= dimethyldithiocarbamate, DEDTC=diethyldithiocarbamate, DBDTC=dibenzoyldithiocarbamate

Scheme 12. Synthesis of gold(I) bis-phosphine complexes (**1-5**)

$(\text{CH}_3)_2\text{SAuCl}$ (**1**)

Complex (**1**) was synthesized by a modified previously reported method [125]. In a fume hood, dimethylsulfide was added dropwise with stirring to reduce a yellow ethanolic $\text{NaAuCl}_4 \cdot 3\text{H}_2\text{O}$ solution at 0-5 °C until a white precipitate was formed. The product was washed twice with ethanol (5 mL) and three times with diethyl ether (10 mL), then dried in the dark and stored in fridge. The yield was 0.268 g (91%). Anal. calc. for $\text{C}_2\text{H}_6\text{SAuCl}$ = 294.55 g/mol: C, 8.35; H 2.13. Found: C, 8.12; H, 1.83. ^1H NMR (CDCl_3 , ppm), δ 2.75 (s, 6H). ^{13}C NMR (CDCl_3 , ppm) δ 25.3.

$[\text{C}_{44}\text{H}_{44}\text{Au}_2\text{Cl}_2\text{N}_2\text{P}_2]$ (**2**)

Precursor (**1**) (295 mg, 1 mmol) in 5 mL of dichloromethane was added dropwise to a solution of *(1R,2R)-N,N-Bis[2-(diphenylphosphino)-benzyl]cyclohexane-1,2-diamine* (331.4 mg, 0.5 mmol) in 10 mL of dichloromethane. A clear colorless solution appeared and was stirred for 30 min; then, the solvent was concentrated by low evaporation at room temperature. The dichloro(bisphosphino)digold(I) intermediate (**2**), was obtained as a white solid, recrystallized from acetone /dichloromethane and dried overnight in vacuum. The yield was 0.479 g (85%). M.P. 127-130 °C. Anal. calc. for $\text{C}_{44}\text{H}_{44}\text{Au}_2\text{Cl}_2\text{N}_2\text{P}_2$ (1127.62 g/mol): C, 46.42; H, 3.39; N, 2.41. Found: C, 46.87; H, 3.93; N, 2.48. IR (cm^{-1}) $\nu(\text{N-H})$ 3442, $\nu(\text{=CH})$ 3055, $\nu(\text{CH}_2)$ 2923_{asym}, 2854_{sym}, $\nu(\text{C-H})$ 1436_{bend}, $\nu(\text{Ar-C=C})$ 1633, $\nu(\text{N-C})$ 1478. ^1H NMR (CDCl_3 , ppm) δ 9.06 (s, NH); 4.79, 4.54 (d, C(1)H, H'); 4.11 (m, C(2)H, H'); 2.31, 2.14 (m, C(3)H); 1.86, 1.32 (m, C(4)H); 6.77-8.25 (m, 28H, C_6H_5). ^{13}C NMR (CDCl_3 , ppm) δ 46.22 C(1); 63.89, 59.05 C(2); 29.68, 29.40; C(3); 23.64, 22.97 C(4); 127.28-163.76 C(C_6H_5). ^{31}P NMR (CDCl_3 , ppm) δ -11.25.

[Au₂(C₄₄H₄₄N₂P₂)(C₂H₆NCS₂)₂] (3)

This complex was prepared by a previously reported method [126], intermediate **(2)** (281.9 mg, 0.25 mmol) in 10 mL of dichloromethane was added to sodium dimethyldithiocarbamate monohydrate (72 mg, 0.5 mmol) in 10 mL of ethanol at room temperature with continuous stirring for 2h. The mixture was filtered, and the clear pale yellow solution was stored for low evaporation. A yellow solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in vacuum. The yield 0.263 g (81%). M.P. 110-112 °C. Anal. calc. for C₅₀H₅₆Au₂N₄P₂S₄ (1297.15 g/mol): C, 46.32; H, 4.31; N, 4.21; S, 9.79. Found: C, 46.29; H, 4.35; N, 4.31; S, 9.88. IR (cm⁻¹) ν (N-H) 3434, ν (CH) 2923; ν (CH₂) 2925_{asym}, 2852_{sym}, ν (C-H) 1435_{bend}; ν (Ar-C=C) 1629; ν (N-C) 1478; ν (C=S) 1099. ¹H NMR (CDCl₃, ppm) δ 1.61 (s, NH); 4.00, 3.81 (d, C(1)H, H'); 3.46 (m, C(2)H, H'); 2.13, 1.62 (m, C(3)H); 1.26, 1.10 (m, C(4)H); 4.35(s, C(6)H); 6.80-7.58 (m, 28H, C₆H₅). ¹³C NMR (CDCl₃, ppm) δ 49.56 C(1); 59.10 C(2); 31.58, 30.93; C(3); 24.84, 22.64 C(4); 207.37 (C=S); 45.37 C(6); 127.24-134.66 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 29.77.

[Au₂(C₄₄H₄₄N₂P₂)(C₄H₁₀NCS₂)₂] (4)

This complex was synthesized with sodium diethyldithiocarbamate trihydrate (112.7 mg, 0.5 mmol) by steps similar to **(3)**. An orange solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.291 g (86%). M.P. 99-101 °C. Anal. calc. for C₅₄H₆₄ Au₂N₄P₂S₄ (1353.25 g/mol): C, 47.63; H, 4.65; N, 4.03; S, 9.21. Found: C, 47.92; H, 4.76; N, 4.14; S, 9.47. IR (cm⁻¹) ν (N-H) 3424, ν (=CH₂) 3052; ν (CH₂) 2925_{asym}, 2853_{sym}, ν (C-H) 1435_{bend}, ν (Ar-C=C) 1587, ν (N-C) 1480, ν (C=S) 1099.

^1H NMR (CDCl_3 , ppm) δ 2.35 (s, NH); 4.07, 3.89 (d, C(1)H, H'); 3.74 (m, C(2)H, H'); 2.08, 1.78 (m, C(3)H); 1.49, 1.02 (m, C(4)H); 4.19 (q, C(6)H); 1.30 (q, C(7)H); 6.74-8.03 (m, 28H, C_6H_5). ^{13}C NMR (CDCl_3 , ppm) δ 50.78 C(1); 61.21 C(2); 30.93 C(3); 24.85 C(4); 205.71 (C=S); 49.31 C(6); 12.28 C(7) 126.71-145 C(C_6H_5). ^{31}P NMR (CDCl_3 , ppm) δ 26.80.

[$\text{Au}_2(\text{C}_{44}\text{H}_{44}\text{N}_2\text{P}_2)(\text{C}_{14}\text{H}_{14}\text{NCS}_2)_2$] (**5**)

This complex was synthesized with sodium dibenzylthiocarbamate trihydrate (153.6 mg, 0.5 mmol) by steps similar to (**3**). A yellow solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.348 g (87%). M.P. 101-103 °C. Anal. calc. for $\text{C}_{74}\text{H}_{72}\text{Au}_2\text{N}_4\text{P}_2\text{S}_4$ (1601.53 g/mol): C, 55.13; H, 4.21; N, 3.11; S, 7.78. Found: C, 55.49; H, 4.53; N, 3.49; S, 8.00. IR (cm^{-1}) $\nu(\text{N-H})$ 3418, $\nu(=\text{CH}_2)$ 3047, $\nu(\text{CH}_2)$ 2920, 2848_{sym}; $\nu(\text{C-H})$ 1443_{bend}, $\nu(\text{Ar-C=C})$ 1639, $\nu(\text{N-C})$ 1203, $\nu(\text{C=S})$ 1099. ^1H NMR (CDCl_3 , ppm) δ 2.62 (s, NH); 4.90, 4.45 (d, C(1)H, H'); 4.22 (m, C(2)H, H'); 2.81, 1.99 (m, C(3)H); 1.59, 1.16 (m, C(4)H); 5.24, 5.07 (d, C(6)H); 6.81-7.91 (m, 38H, C_6H_5). ^{13}C NMR (CDCl_3 , ppm) δ 51.19 C(1); 63.99 C(2); 29.40 C(3); 24.01 C(4); 198.54 (C=S); 56.14 C(6); 12.28 C(7) 127.94-136.71 C(C_6H_5). ^{31}P NMR (CDCl_3 , ppm) δ 23.00.

3.2.2 [Au₂(Bis[(2-diphenylphosphino)ethyl]ammonium chloride)Cl₂] with dialkyl and diaryldithiocarbamates (6-9)

[Au₂(C₂₈H₃₀ClNP₂)Cl₂] (**6**)

This complex was synthesized with *bis*[(2-diphenylphosphino)ethyl]ammonium chloride (239 mg, 0.5 mmol) by a procedure similar to (**2**). A white solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.391 g (83%). M.P. 159-161 °C. Anal. calc. for C₂₈H₃₀Au₂Cl₃NP₂ (942.78 g/mol): C, 35.11; H, 2.99; N, 1.31. Found: C, 35.67; H, 3.20; N, 1.48. IR (cm⁻¹) ν(N-H) 3429, ν(=CH) 3051, ν(CH₂) 2936, ν(C-H) 1315_{bend}, ν(Ar-C=C) 1625, ν(N-C) 1435. ¹H NMR (CDCl₃, ppm) δ 10.10(s, NH); 3.67, 3.17 (m, C(1)H, H'); 2.81, 2.16 (m, C(2)H, H'); 7.42-7.70 (m, 20H, C₆H₅). ¹³C NMR (CDCl₃, ppm) δ 44.04 C(1), 25.18 C(2), 126.98-133.45 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 21.90.

Scheme 13. Synthesis of gold(I) bis-phosphine complexes (**6-9**).

[Au₂(C₂₈H₃₀ClNP₂)(C₂H₆NCS₂)₂] (7)

This complex was synthesized with sodium dimethyldithiocarbamate monohydrate (71.6 mg, 0.5 mmol) by a procedure similar to (3). A yellow solid was obtained, it was recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.225 g (81%). M.P. 99-101 °C. Anal. calc. for C₃₄H₄₂Au₂ClN₃P₂S₄ (1112.31 g/mol): C, 36.33; H, 3.45; N, 3.31; S, 11.21. Found: C, 36.71; H, 3.80; N, 3.77; S, 11.53. IR (cm⁻¹) ν(N-H) 3420, ν(=CH₂) 3045, ν(CH₂) 2920, ν(C-H) 1242_{bend}, ν(Ar-C=C) 1629, ν(N-C) 1490, ν(C=S) 1108. ¹H NMR (CDCl₃, ppm) δ 9.45 (s, NH); 3.92, 3.21 (m, C(1)H, H'); 2.99, 2.10 (m, C(2)H, H'), 3.56(s, C(4)H), 7.50-7.75 (m, 20H, C₆H₅). ¹³C NMR (CDCl₃, ppm) δ 43.81 C(1), 22.68 C(2), 201.49 C=S(3), 45.66 C(4), 124.63-132.69 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 27.50.

[Au₂(C₂₈H₃₀ClNP₂)(C₄H₁₀NCS₂)₂] (8)

This complex was synthesized with sodium diethyldithiocarbamate trihydrate (112.7 mg, 0.5 mmol) by a procedure similar to (3). An orange solid was obtained, it was recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.248 g (85%). M.P. 95-97 °C. Anal. calc. for C₃₈H₅₀Au₂ClN₃P₂S₄ (1168.42 g/mol): C, 38.93; H, 4.00; N, 3.32; S, 10.41. Found: C, 39.06; H, 4.31; N, 3.59; S, 10.97. 3.3 Synthesis of gold(I) complexes with mono-phosphine and dithiocarbamate ligands

3.3.1 Chlorido(2-(diphenylphosphino)ethylamine)Au(I) with dialkyl and dibenzyl-dithiocarbamates (18-22)

Scheme 16. Synthesis of gold(I) polymers (**19-21**) and gold(I) monophosphine complexes **18** and **22**.

[C₁₄H₁₆NPAuCl] complex (**18**)

This complex was synthesized with 2-(*diphenylphosphino*)ethylamine (114.6 mg, 0.5 mmol) by a procedure similar to (**2**). The chlorido(2-(*diphenylphosphino*)ethylamine)-gold(I) was obtained as a white solid, recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.196 g (85%). Anal. calc. for C₁₄H₁₆NPAuCl (461.68 g/mol): C, 36.42; H, 3.39; N, 3.03. Found: C, 35.90; H, 2.84; N, 3.36. IR (cm⁻¹) ν (N-H) 3431, 3354; ν (CH₂) 2917_{asym}, 2857_{sym}, ν (C-H) 1310_{bend}; ν (Ar-C=C) 1603; ν (N-C) 1432. ¹H NMR (CDCl₃, ppm) δ 4.03 (s, NH); 3.31, 3.17 (m, C(1)H, H'); 2.97, 2.73 (m, C(2)H, H'); 7.45-7.65 (m, 10H, C₅H₅). ¹³C NMR (CDCl₃, ppm) δ 37.65 C(1), 31.50 C(2), 129.28-133.26 C(C₅H₅). ³¹P NMR (CDCl₃, ppm) δ 21.39.

[Au₂(C₂H₆NCS₂)₂]_n polymer (**19**)

Intermediate (**18**), (231 mg, 0.5 mmol) in 10 mL of dichloromethane was added to sodium dimethyldithiocarbamate monohydrate (74.5 mg, 0.52 mmol) in 10 mL of ethanol at room temperature with continuous stirring for 6h. A colorless solid (2-(*diphenylphosphino*)-ethylamine) that formed was filtered off, and the clear pale yellow solution was stored for low evaporation. A yellow solid was obtained. IR (cm⁻¹) ν (C-H) 2990, ν (C-H) 1375_{bend}; ν (N-C) 1483; ν (C=S) 1100, 993. ¹H NMR (CDCl₃, ppm) δ 3.55 (s, 6H, CH₃). ¹³C NMR (CDCl₃, ppm) δ 196.12-NCS₂(1), 46.64 C(2).

[Au₂(C₄H₁₀NCS₂)₂]_n polymer (**20**)

This polymer was synthesized with sodium diethyldithiocarbamate trihydrate (117.2 mg, 0.52 mmol) by a procedure similar to (**18**). After 3 days, needle-like orange crystals were

obtained. A suitable crystal was selected for X-ray diffraction analysis. IR (cm⁻¹) $\nu(\text{C-H})$ 2970, $\nu(\text{C-H})$ 1377_{bend}; $\nu(-\text{CH}_2)$ 2925_{asym}, 2856_{sym}; $\nu(-\text{CH}_2)$ _{bend} 1264; $\nu(\text{N-C})$ 1480; $\nu(\text{C=S})$ 1098, 1067. ¹H NMR (CDCl₃, ppm) δ 3.92 (t, 6H, CH₃), (t, 4H, CH₂CH₃). ¹³C NMR (CDCl₃, ppm) δ 205.58 -NCS₂ (1), 49.35 C(2), 12.20 C(3).

[Au₂(C₁₄H₁₄NCS₂)₂]_n polymer (**21**)

This polymer was synthesized with sodium dibenzylidithiocarbamate trihydrate (159.7mg, 0.52 mmol) by a procedure similar to (**18**). A yellow solid was obtained. IR (cm⁻¹) $\nu(\text{CH}_2)$ 2923_{asym}, 2850_{sym}, $\nu(\text{C-H})$ 1265_{bend}; $\nu(\text{Ar-C=C})$ 1602; $\nu(\text{N-C})$ 1433; $\nu(\text{C=S})$ 1100, 1072. ¹H NMR (CDCl₃, ppm) δ 4.85, 4.78 (d, 4H, CH₂), 7.17-7.77(m, 10H, C₅H₅). ¹³C NMR (CDCl₃, ppm) δ 210.80 -NCS₂ (1), 54.27 C(2), 128.58-140.93 C(C₆H₅).

[Au(C₁₄H₁₆NP)₂]₂Cl complex (**22**)

Intermediate (**18**), (231 mg, 0.5 mmol) in 10 mL of dichloromethane was added to 2-(Diphenylphosphino)ethylamine (114.6 mg, 0.5 mmol) in 10 mL of dichloromethane at ambient room temperature with continuous stirring for 6h. A colorless solution was filtered off and stored for slow evaporation. A colorless solid was obtained. Yield 0.3g (87%). Anal. calc. for [Au(C₂₈H₃₂NP)₂]₂Cl (690.68 g/mol): C, 48.67; H, 4.67; N, 4.05. Found: C, 47.89; H, 5.52; N, 4.04. IR (cm⁻¹) $\nu(\text{N-H})$ 3421, 3332; $\nu(\text{CH}_2)$ 2909_{asym}, 2852_{sym}, $\nu(\text{C-H})$ 1275_{bend}; $\nu(\text{Ar-C=C})$ 1566; $\nu(\text{N-C})$ 1496. ¹H NMR (CDCl₃, ppm) δ 4.04, 3.13 (s, 2H, NH); 3.02, 2.85 (m, C(1)H, H'); 2.56, 1.26 (m, C(2)H, H'); 7.33-7.74 (m, 20H, C₅H₅). ¹³C NMR (CDCl₃, ppm) δ 36.63 C(1), 28.57 C(2), 129.17-133.08 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 26.55.

3.3.2 Chlorido((1R,2R)-2-(diphenylphosphino)-2,3-dihydro-1H-inden-1-amine)Au(I) with dialkyl and dibenzyl-dithiocarbamate complexes (23-26)

Scheme 17. Synthesis of gold(I) mono-phosphine complexes (23-26).

[Au(C₂₁H₂₀NP)Cl] complex (23)

This complex was synthesized with (1R,2R)-2-(diphenylphosphino)-2,3-dihydro-1H-inden-1-amine (158.7 mg, 0.5 mmol) by a procedure similar to (2). A white solid was obtained, it was recrystallized from acetone/dichloromethane and dried overnight in a vacuum. Yield 0.451 g (78%). Anal. calc. for C₂₁H₂₀NPAuCl (549.78 g/mol): C, 45.78; H,

3.66; N, 2.54. Found: C, 45.27; H, 3.13; N, 2.18. IR (cm⁻¹) ν (N-H) 3461, 3334; ν (CH₂) 2935_{asym}, 2850_{sym}, ν (C-H) 1280_{bend}, ν (Ar-C=C) 1628, ν (C-N) 1475. ¹H NMR (CDCl₃, ppm) δ 1.56 (s, NH), 4.20 (d, C(1)H); 2.17 (m, C(2)H); 3.33, 2.75 (m, C(3)H,H'), 7.20-7.89 (m, 14H, C₆H₅). ¹³C NMR (CDCl₃, ppm) δ 56.5 C(1), 46.7 C(2), 30.8 C(3), 126.3-139.8 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 36.18.

[Au(C₂₁H₂₀NP)(C₂H₆NCS₂)] (24)

This complex was synthesized with sodium dimethyldithiocarbamate monohydrate (71.6 mg, 0.5 mmol) by a procedure similar to (3). Pale yellow solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in a vacuum. Yield 0.238 g (75%). Anal. calc. for C₂₄H₂₆AuN₂PS₂ = 634.55 g/mol: C, 45.78; H, 4.12; N, 4.41; S, 10.10. Found: C, 45.37; H, 4.55; N, 3.89; S, 9.83. IR (cm⁻¹) ν (N-H) 3447, 3342; ν (CH₂) 2927_{asym}, 2851_{sym}, ν (C-H) 1244_{bend}, ν (Ar-C=C) 1615, ν (C-N) 1486, ν (C=S) 1099, 1134. ¹H NMR (CDCl₃, ppm) δ 1.63 (s, NH), 4.48 (d, C(1)H); 2.16 (m, C(2)H); 3.43, 3.17 (m, C(3)H,H'), 3.40 (s, C(4)H), 7.40-8.57 (m, 14H, C₆H₅). ¹³C NMR (CDCl₃, ppm) δ 56.9 C(1), 32.5 C(2), 29.7 C(3), 184.0 C=S(4), 34.7 C(5), 125-140 C(C₆H₅). ³¹P NMR (CDCl₃, ppm) δ 33.67.

[Au(C₂₁H₂₀NP)(C₄H₁₀NCS₂)] (25)

This complex was synthesized with sodium diethyldithiocarbamate trihydrate (112.7 mg, 0.5 mmol) by a procedure similar to (3). An orange solid was obtained, recrystallized from acetone/dichloromethane and dried overnight in vacuum. Yield 0.262 g (79%). Anal. calc. for C₂₆H₃₀AuN₂PS₂ (662.60 g/mol): C, 47.13; H, 4.56; N, 4.23; S, 9.68. Found: C, 45.37;

H, 4.10; N, 3.87; S, 9.13. 3.4. Single crystal structure determination

Suitable crystals of complex (**27**) were obtained as colorless rods from dichloromethane/ethanol. The X-ray data were collected at 173K (-100°C) on a STOE IPSD 2 Image Plate Diffraction System [127] connected with a two-circle goniometer and using MoK α graphite monochromator (λ = 0.71073 Å). The structure was solved by SHELXS-2014 program [128]. The refinement and further calculations were carried out with SHELXL-2014 [128].

The water H atoms were located in a difference Fourier map and refined with distance restraint of O-H = 0.84(2) Å and with $U_{iso}(H) = 1.5U_{eq}(O)$. It was not possible to locate both H atoms on water molecules O7W and O8W. The non-hydrogen atoms were refined using least-squares matrix on F^2 . A semi-empirical absorption correction was applied using the MUL scan ABS routine in PLATON [129]. The crystal structure and crystal packing were drawn using Mercury software [130]. The symmetry of crystal data and structure refinement is demonstrated in Table 3.23.

3.5 MTT assay for in vitro cytotoxicity of gold(I) complexes

Gold(I) complexes (**2-17**), (**19-22**), (**24-26**) and (**36, 37**) were tested for their *in vitro* cytotoxic effects against MCF7 (human breast cancer), HCT15 (human colon

adenocarcinoma) and A549 (human lung carcinoma) cell lines as previously reported method [131]. The cells were seeded at 3×10^3 cells/well in 100 μ L of DMEM containing 10% fetal bovine serum (FBS) in a 96-well tissue culture plate and incubated for 72 h at 37 °C, 5% CO₂ and 90% relative humidity in a CO₂ incubator. After incubation, 100 μ L of 50, 25 and 12.5 μ M solutions of cisplatin, gold(I) complexes **(2-17)**, **(19-22)**, **(23-26)** and **(36, 37)** prepared in Dulbecco's Modified Eagle's Medium (DMEM), was added to the cells and the cultures were incubated for 24 h. The medium in the wells was casted off and 100 μ L of DMEM containing MTT (0.5 mg/ml) was added to the wells, with subsequent incubation in the CO₂ incubator at 37 °C in the dark for 4 h. After incubation, purple-colored formazan produced by the cells appeared as dark crystals in the bottom of the wells. The culture medium was carefully removed from each well to prevent disruption of the monolayer and 100 μ L of dimethyl sulfoxide (DMSO) was added in each well. The solution in the wells was thoroughly mixed to dissolve the formazan crystals which produce a purple solution. The absorbance of the 96 well-plates was measured at 570 nm with Labsystems Multiskan EX ELISA reader against a reagent blank. The experimental results are calculated as micro-molar concentration of 50% cell growth inhibition (IC₅₀) of each drug. The MTT assay was carried out in three independent experiments, each in triplicate.

3.6 Results and Discussion

3.6.1 Gold(I) complexes with mixed bis-phosphine and dithiocarbamates ligands (2-17)

3.6.1.1 Spectroscopic analysis

The synthesized gold(I) complexes with mixed bis-phosphine dithiocarbamate ligands (2-17) are shown in (Schemes 12, 13, 14 and 15) were characterized by ^1H , ^{13}C and ^{31}P NMR, mid/far FT-IR spectroscopy, elemental analysis and melting point. The FT-IR data of free ligands and complexes (2-17) are summarized in Table 3.1.

The spectra present the characteristic $\nu(\text{C}-\text{N})$ and $\nu(\text{C}-\text{S})$ absorbance bands. The region around 1500 cm^{-1} is associated with a thioureido ion ($\text{RN}^+=\text{CS}_2$) intermediate between the C-N single bond ($1250\text{-}1360\text{ cm}^{-1}$) and the C=N double bond ($1640\text{-}1690\text{ cm}^{-1}$) in the dithiocarbamate complexes. The strong $\nu(\text{C}-\text{N})$ absorbance bands of the complexes (2-17) were assigned in the range $(1403\text{-}1480)\text{ cm}^{-1}$, suggesting partial double bond character due to a partially delocalized electron density [132-134].

The $\nu(\text{C—H})$ sp^3 stretching band was observed at 2924 and 2925 cm^{-1} for free methyl and ethyl dithiocarbamate ligand, respectively, and after coordination, it was observed at 2934 and 2970 cm^{-1} . The $\nu(\text{C=S})$ stretching band for free ligand was observed at 926-986 cm^{-1} , and after coordination it was observed at 1099-1118 cm^{-1} . The $\nu(\text{C=C})$ band observed in the region 1587–1635 cm^{-1} of these complexes, which were assigned to the presence of aromatic ring.

The comparison of ^1H NMR spectra between free dithiocarbamate ligand and their complexes (**2-17**) showed significant shifts that indicate complexation of dithiocarbamate, as shown in Table 3.2.

The ^{13}C NMR chemical shifts (Table 3.3) for these complexes showed significant shift to higher fields with respect to free dithiocarbamate ligands. For example, C=S chemical shifts for dimethyldithiocarbamate, diethyldithiocarbamate or dibenzylthiocarbamate were observed in the range 206-213 ppm compared to their gold(I) complexes, with a range of 198-210 ppm due to back donation from metal to ligand. In addition, ^{31}P NMR chemical shifts for gold(I) complexes showed significant shift to lower field at (23.00 to 39.20 ppm), relatively to their precursors (**2**, **6**, **10** and **14**) with a range (-11.26 to 21.90 ppm) as shown in Table 3.3.

3.6.1.2 *In vitro* cytotoxic activities for gold(I) bisphosphine complexes (2-17)

In the present study, the synthesized gold(I) bis-phosphine complexes (**2**, **5**, **6**, **9**, **10**, **13**, **17**) compared to *cisplatin* (standard classical anticancer drug) were tested *in vitro* cytotoxicity against A549, MCF7 and HCT15 human cancer cell lines using an MTT assay.

The study of the dose-dependent inhibition of cell proliferation was obtained by increasing *cisplatin* and complex (**2-17**) concentrations against a fixed number of three human cancer cell lines as shown in Figures 3.1-3.3. IC₅₀ values were obtained from the plot of the *cisplatin* and gold(I) complexes (**2-17**) concentration against the percentage of cell viability as shown in Table 3.4. For the A549 cell line, the complexes (**2**, **6**) exhibited IC₅₀ values 42 ± 0.5 and 43 ± 0.3 μM , respectively, similar to *cisplatin* (42 ± 2 μM). These data clearly show that the complexes (**2-17**) inhibit cell proliferation and have potency levels similar to *cisplatin*, suggesting that the presence of the P-Au-S moiety enhanced the activity of these complexes [135]. For HCT15 and MCF7 cell lines, all complexes showed moderate to higher IC₅₀ values with respect to *cisplatin*.

Table 3.4. IC₅₀ values (μM) of gold(I) complexes (**2-17**) against HCT15, A549 and HeLa cancer cell lines.

Complex	HCT15	A549	MCF7
Cisplatin	32 ± 2	42 ± 2	23 ± 4
2	76 ± 0.5	42 ± 0.5	82 ± 2
5	53 ± 3	291 ± 5	116 ± 3
6	46 ± 1	43 ± 0.3	36 ± 2
9	44 ± 3	206 ± 2	121 ± 3
10	58 ± 2	74 ± 1	53 ± 1
13	51 ± 3	280 ± 4	133 ± 2
17	51 ± 1	379 ± 8	142 ± 4

3.6.2 Gold(I) complexes with mixed mono-phosphine and dithiocarbamate ligands (18-22), (23-26), (27-30) and (31-34)

3.6.2.1 Spectroscopic analysis

The synthesized of complexes (18-22), (23-26), (27-30) and (31-34) are shown in (Schemes 16, 17, 18 and 19) and were characterized by ^1H , ^{13}C and ^{31}P NMR and mid FT-IR spectroscopy, elemental analyses and single crystal X-ray diffraction analysis.

The FT-IR spectra for free ligands and their complexes (18-22), (23-26), (27-30) and (31-34) are summarized in Tables 3.5-3.6, 3.8 and 3.10. The formation of the complexes was confirmed by the presence of the $\nu(\text{C}-\text{N})$ and $\nu(\text{C}-\text{S})$ absorbance bands. The region around 1500 cm^{-1} is associated with thioureido ion ($\text{RN}^+=\text{CS}_2$) between the $\text{C}-\text{N}$ single bond ($1250\text{-}1360\text{ cm}^{-1}$) and the $\text{C}=\text{N}$ double bond ($1640\text{-}1690\text{ cm}^{-1}$) in the dithiocarbamate complexes [136, 132]. The strong $\nu(\text{C}-\text{N})$ absorbance bands of the complexes (19, 24, 28 and 32-34) were assigned in range of ($1499\text{-}1433\text{ cm}^{-1}$), suggesting partial double bond character due to a partially delocalized electron density [136].

For the (CS_2) stretching, two bands were observed for the complexes (19, 24, 28 and 32-34) in the range of ($1134, 1099\text{ cm}^{-1}$) to ($1098, 973\text{ cm}^{-1}$) with medium intensity. The presence of these two bands confirmed (CS_2)_{as} and (CS_2)_s of the dithiocarbamate ligand having bidentate nature [137-138].

The bands showed in the region of $1533\text{ to }1629\text{ cm}^{-1}$, which were assigned to $\nu(\text{C}=\text{C})$ of the aromatic ring [134].

In Far IR spectra, two bands of $\text{Au}-\text{Cl}$ are observed at 220 and 250 cm^{-1} for intermediates 23 and 27 respectively, while they not for their complexes (24-26) and (28-30) and new

bands are observed in the range of 272 and 278 cm^{-1} attributed Au—S band as shown in Tables 3.7 and 3.9.

The ^{13}C NMR chemical shifts for the complexes (**18-34**) showed significant shifts to up fields with respect to free dithiocarbamate ligands. For instance, $\text{C}=\text{S}$ chemical shifts for dimethyldithiocarbamate, diethyldithiocarbamate and dibenzylthiocarbamate were observed in the range 206–213 ppm compared to their coordinated complexes in the range 184–210 ppm. ^{31}P NMR chemical shifts for precursors **18**, **31** and ligands **L1**, **L2**, respectively, compared to their dithiocarbamate complexes showed significant shifts

downfield, due to back donation from filled d-orbitals of gold atom to empty π^* of S—C bond of dithiocarbamate moiety as shown in Tables 3.15-3.18.

The crystal structure of the gold(I) polymer (**19**) $[\text{Au}_2(\text{C}_4\text{H}_{10}\text{NCS}_2)_2]_n \cdot x\text{CH}_2\text{Cl}_2$ has been recently published [139].

3.6.2.2 Gold(I) phosphine complexes (35-37)

The synthesized complexes (**35-37**) are shown in (Scheme 20) and were characterized by ^1H , ^{13}C and ^{31}P NMR and mid FT-IR spectroscopy, elemental analyses.

The $\nu(\text{C}-\text{H})$ sp^2 bending of precursor **35** was observed at 1370 cm^{-1} which is shifted to lower region in complexes **36** and **37** at 1360 and 1365 cm^{-1} , respectively. The $\nu(\text{C}=\text{C})$ stretching appears at 1623 cm^{-1} in precursor **35**, whereas for **36-37** it is observed at 1589 and 1585 cm^{-1} , respectively, as shown in Table 3.19.

^1H NMR spectra shows a significant shift for precursor **35** with respect to complexes **36-37** Table 3.20. ^{31}P NMR resonance of complexes **36-37** observed at 4.96 and $(12.57, 29.61)$ ppm were shifted upfield with respect to precursor **35** (36.18 ppm) due to back donation from gold center atom to empty π^* of $\text{P}-\text{C}$ bond as illustrated in Table 3.21.

3.6.3 Single crystal X-ray structure of complex **27**

The molecular structure of complex $[\text{Au}(\text{C}_{18}\text{H}_{22}\text{NP})\text{Cl}]$ (**27**) is depicted in Figures 3.4- and 3.5. Selected bond lengths and bond angles for complex **27** are shown in Table 3.22 and structure refinement & the crystal data are given in Table 3.23. The coordination geometry around the gold central atom is close to linearity, with (P1—Au—Cl1) $176.8 (1)^\circ$. The Au1—P1 and Au1—Cl1 bond lengths are 2.24 (2) and 2.28 (3) Å, respectively. The bond lengths and bond angles are similar to that reported for similar compounds [140-141].

Figure 3.4. Molecular structure of complex **27**, with partial labelling atoms and 50% probability ellipsoids.

3.6.4 *In vitro* cytotoxic activities of gold(I) monophosphine complexes (**18-22**, **35** and **37**)

In the present study, the precursors (**18**, **35**), gold(I) polymers (**19-21**) and complexes (**22**, **37**) were tested for *in vitro* cytotoxicity against A549, MCF7 and HCT15 human cancer cell lines using an MTT assay and compared to that of *cisplatin*.

The dose-dependent inhibition of cell proliferation was obtained by specific increase of complex concentrations against a fixed number of three human cancer cell lines Figures (3.6-3.8). IC₅₀ values were obtained from the plot of the complex concentration against

the percentage of cell viability (Table 3.24). For the A549 cell line, the IC₅₀ values for polymers (**20**, **21**) and complex (**22**) were 20 ± 1, 29 ± 2, 34 ± 1 µM, respectively, compared to *cisplatin* at 42 ± 2 µM. These data clearly show that polymers (**20**, **21**) and complex (**22**) have inhibition of cell proliferation and potency levels one to two times better than that exhibited by *cisplatin*, suggesting the presence of the labile dithiocarbamate in (**20**, **21**) and two phosphine ligands around gold ion in complex **22** enhanced the activity of these complexes [135]. Polymer (**20**) was the most active among the series, exhibiting IC₅₀ = 20 ± 1 µM due to the labile diethyldithiocarbamate ligand bonded to the gold(I) center. Gold(I) polymer (**20**) and complexes (**22**, **37**) showed moderate IC₅₀ values with respect to cisplatin and the other gold(I) dithiocarbamate complexes reported for their activity against HCT15 cell line [126]. For the MCF7 cell line, all complexes exhibited higher IC₅₀ values than the standard *cisplatin* IC₅₀ values.

Table 3.24. IC₅₀ values (µM) of gold(I) complexes (**18-22**, **35** and **37**) against HCT15, A549 and HeLa cancer cell lines.

Complex	HCT15	A549	MCF7
Cisplatin	32 ± 2	42 ± 2	23 ± 4
18	51 ± 1	54 ± 1	38 ± 1
19	257 ± 4	304 ± 6	139 ± 5
20	39 ± 2	20 ± 1	49 ± 2
21	69 ± 3	29 ± 2	76 ± 3
22	34 ± 2	34 ± 1	52 ± 2
35	92 ± 2	97 ± 1	95 ± 3
37	37 ± 1	49 ± 1	48 ± 2

CHAPTER 4

SYNTHESIS, CHARACTERIZATION AND *IN VITRO* CYTOTOXIC EVALUATION OF GOLD(I) CARBENE COMPLEXES WITH SELONE LIGANDS

4.1 Introduction

Gold complexes bearing N-Heterocyclic carbene (NHC) ligands have gained much attention due to their important applications in medicine, catalysis, anticancer and antimicrobial activity [142-145]. Since these ligands were first synthesized by Arduengo, a number of NHCs metal complexes are extensively used for catalysis, biochemistry and anticancer treatments [146-149]. NHC ligands form stable complexes with metal ions via σ -donation stronger than π -back donation [150].

Selenocysteine is the active side of selenoenzymes such as glutathione peroxidase (GPx), which is used to protect different organisms from damage due to catalytic cycle to reduce harmful peroxidase [151-153]. Spectroscopic properties of selenocyanide ligand with some transitional metals have been investigated [154]. The interaction of Au(III) compound with two equivalents of this ligand resulted in reduction of Au(III) to Au(I). In addition, Brendenkamp et al. studied the reactivity of N-selenocarbamyl benzamidin with

Ni(II), Pd(II) and Au(III) compounds [155]. A number of seleno-metal compounds were reported as potentially a promising new class of drugs for instance, gold antimalarial drug [156], Cd/Hg antibacterial [157,117], ruthenium antitumor agent [158] and Pt(II)/Pd(II) anticancer agents [159].

4.2. Experimental Section

4.2.1 Materials and Instrumentation

All chemicals and solvents are analytical grade, they were used without further purification. AgPF₆, selenourea, N,N-dimethylthiourea, 1,3-bis(2,6-di-isopropylphenyl)-imidazol-2-ylidenegold(I)chloride [Au(Ipr)Cl], and all organic solvents were purchased from Sigma -Aldrich St. Louis, Missouri United States and Stream Chemicals, Massachusetts, United States. ImSe, Diaz-Se, Diap-Se and their derivatives were synthesized according to methods in the literature [160-161].

¹H, ¹³C NMR and FTIR spectroscopy along with elemental analysis instruments were mentioned previously in section 3.1.

⁷⁷Se NMR spectra were recorded on a LAMBDA 500 spectrophotometer operating at 200.0 MHz. ¹³C (MAS) NMR results were recorded on a Bruker 400 MHz spectrometer at ambient room temperature of 25 °C. Samples were packed into 4 mm zirconium oxide rotors. Pulse delay of 7.0 s and a contact time of 5.0 ms. The magic angle spinning rates were 4 and 8 kHz. Carbon chemical shifts were measured relative to adamantane at 38.56 ppm.

4.2.2 Synthesis of gold(I) carbene complexes with selones (39-50)

Scheme 21A. Synthesis of gold(I)-selone complexes (**39-43**).

Scheme 21A. Synthesis of gold(I)-selone complexes (**44-49**).

Scheme 21C. Synthesis of gold(I)-selone complex **50**.

$[\text{Au}(\text{Ipr})(\text{SeCN}_2\text{C}_4\text{H}_{10})]\text{PF}_6$ (**39**)

This complex was synthesized using a modified previously reported method [138]. AgPF_6 (127 mg, 0.5 mmol) was dissolved in 5 mL of ethanol and added to 1,3-Bis(2,6-di-isopropylphenyl)imidazol-2-ylidenegold(I)chloride $[\text{Au}(\text{Ipr})(\text{Cl})]$ (311 mg, 0.5 mmol) in 5 mL of CH_2Cl_2 . Then stirred for 5 min at room temperature and filtered off. N-ethyl,-1,3-imidazolidine-2-selone (*N-EtImSe*) (88.6 mg, 0.5 mmol) was added to the filtrate, stirred for 1 hour and filtered. The formed complex was kept in undisturbed area, after three days bright gray crystals were obtained and a suitable crystal was selected for single crystal diffraction analysis. Yield 0.264 g (60%). Anal calc. for $\text{C}_{32}\text{H}_{46}\text{AuN}_4\text{SePF}_6$ (907.62 g/mol): C, 42.39; H, 5.11; N, 6.18. Found: C, 42.43; H, 5.83; N, 6.46.

[Au(Ipr)(SeCN₂C₃H₈)]PF₆ (40)

This complex was synthesized with 1,3-diazinane-2-selone (DiazSe) by a procedure similar to (39). After four days a yellowish-white solid was obtained. The yield was 0.180 g (50%). Anal. calc. for C₃₁H₄₄AuN₄SePF₆ (893.60 g/mol): C, 41.71; H, 4.97; N, 6.28. Found: C, 41.92; H, 5.14; N, 6.82.

[Au(Ipr)(SeCN₂C₄H₁₀)]PF₆ (41)

This complex was synthesized using 1,3-diazepine-2-selone (DiapSe) by a procedure similar to (39). After five days white solid was obtained. The yield was 0.275 g (65%). Anal. calc. for C₃₂H₄₆AuN₄Se.PF₆ (907.62 g/mol): C, 42.39; H, 5.11; N, 6.18. Found: C, 41.93; H, 5.26; N, 6.08.

[Au(Ipr)(SeCN₂C₅H₁₂)]PF₆ (42)

This complex was synthesized with N-propyl-1,3-imidazolidine-2-selone (N-Pr-Imse) by a procedure similar to (39). After three days a gray solid was obtained. The yield was 0.240 g (55%). Anal. calc. for C₃₃H₄₈AuN₄SePF₆ (921.65g/mol): C, 43.05; H, 5.25; N, 6.09. Found: C, 42.57; H, 5.51; N, 5.81.

[Au(Ipr)(SeCN₂C₄H₁₀)]PF₆ (43)

This complex was synthesized using N-methyl-1,3-diazinane-2-selone (N-MeDiazSe) by a procedure similar to (39). After four days a pale red solid was obtained. The yield was 0.274 g (60%). Anal calc. for C₃₂H₄₆AuN₄SePF₆ (907.63g/mol): C, 42.39; H, 5.11, N 6.18; found: C 41.98, H 5.38, N 6.16.

[Au(Ipr)(SeCN₂H₄)]PF₆ (44)

This complex was synthesized with selenourea by a procedure similar to (39). After four days colorless crystals were obtained and a suitable crystal was selected for single crystal diffraction analysis. The yield was 0.313 g (75%). Anal. calc. for C₂₈H₄₀AuN₄SePF₆ (853.53 g/mol): C, 39.40; H, 4.72; N, 5.56. Found: C, 41.04; H, 5.23; N 6.04.

[Au(Ipr)(SeCN₂C₂H₆)]PF₆ (45)

This complex was synthesized using 1,3-imidazolidine-2-selone by a procedure similar to (39). After four days a white solid was obtained. The yield was 0.248 g (56%). Anal. calc. for C₃₀H₄₂AuN₄SePF₆ (879.57 g/mol): C, 40.97; H, 4.81; N, 6.37. Found: C, 41.38; H, 4.64; N, 6.28.

[Au(Ipr)(SeCN₂C₄H₁₀)]PF₆ (46)

This complex was synthesized using N,N'-dimethyl-1,3-imidazolidine-2-selone (N,N'-ImSe) by a procedure similar to (39). After four days, brick-red crystals were obtained and a suitable crystal was selected for single crystal diffraction analysis. The yield was 0.265 g (60%). Anal. calc. for C₃₂H₄₆AuN₄SePF₆ (907.63 g/mol): C, 42.35; H, 5.11; N, 6.17. Found: C, 42.68; H, 5.21; N 5.91.

[Au(Ipr)(SeCN₂C₃H₇(OH)))]PF₆ (47)

This complex was synthesized using 5-hydroxy-1,3-diazinane-2-selone by a procedure similar to (39). After five days a gray solid was obtained. The yield was 0.250 g (55%).

Anal. calc. for $C_{31}H_{44}AuN_4SePF_6$ (909.60 g/mol): C, 41.67; H, 4.96; N, 6.30. Found: C, 41.60; H, 4.92; N, 5.99.

[Au(Ipr)(SCN₂C₂H₈)PF₆ (48)

This complex was synthesized using N,N'-dimethyl-thiourea by a procedure similar to (39). After five days colorless crystals were obtained and the suitable crystal was selected for single crystal diffraction analysis. The yield was 0.245g (61%). Anal. calc. for $C_{30}H_{44}AuN_4S.PF_6$ = 881.59 g/mol: C, 41.69; H 5.10; N, 6.94; S, 3.97. Found: C, 41.26; H, 5.57; N, 7.20; S, 3.66.

[Au(Ipr)(SeCN₂C₅H₁₂)PF₆ (49).

This complex was synthesized with N-isopropyl-1,3-imidiazolidine-2-selone (N-isopr-ImSe) by a procedure similar to (39). After four days gray crystals were obtained and a suitable crystal was selected single crystal diffraction analysis. The yield was 0.220g (50%). Anal. calc. for $C_{33}H_{48}AuN_4SePF_6$ (921.65 g/mol): C, 43.00; H, 5.25; N, 6.08. Found: C, 42.93; H, 5.56; N, 6.20.

[Au(Ipr)(SeCN₂C₆H₁₄)PF₆ (50)

This complex was synthesized using N,N'-diethyl-1,3-imidiazolidine-2-selenone by a procedure similar to (39). After four days yellow solid was obtained. The yield was 0.284 g (61%). Anal. calc. for $C_{34}H_{50}AuN_4SePF_6$ (935.68 g/mol): C, 43.64; H, 5.39; N, 5.99. Found: C, 43.19; H, 5.71; N, 5.49.

4.3 Results and Discussion

4.3.1 Spectroscopic characterizations

The synthesized complexes (**39-50**) are shown in (Scheme 21) and were characterized by ^1H , ^{13}C and ^{31}P NMR and mid FT-IR spectroscopy, elemental analyses and single crystal X-ray diffraction analysis.

FT-IR spectra for free ligands and gold(I) complexes (**39-50**) clearly show a significant shift between the ligands and their complexes (**39-50**) inconsistency with complexation as shown in Table 4.1. For instance, $\nu(\text{C}=\text{Se})$ for free ligands is in the range of (588-636) cm^{-1} , while for the complexes (**39-50**) it is in the range (554-557) cm^{-1} . This is consistent with back donation to π^* C=Se [103-105].

The stretching bands of $\nu(\text{N}-\text{H})$ and $\nu(\text{O}-\text{H})$ were shifted to higher frequency in complexes relative to the free ligands due to increase C-N π bond character [64].

^1H NMR data for the ligands and their complexes (**38-50**) are shown in Table 4.2.

^{13}C NMR chemical shift of Au=C in the precursor (**38**) was observed at 175.3 ppm and it is shifted downfield in complexes (**39-50**) in the range of (181.1-185.3) ppm. This deshielding is related to back donation from d-orbital of Au atom to π^* C=Se [92]. The chemical shift of C=Se in all free ligands was observed in the range of (167.4-182.1 ppm), with an up-field shift in their complexes (**39-50**) in the range of (159.8-178.3 ppm) due to more electron shielding C=Se by back donation from d-orbital of gold atom [92,100,162]. ^{13}C NMR results of free ligands and their complexes (**38-50**) are shown in Table 4.3.

Table 4.1. Mid FT-IR frequencies (cm⁻¹) of free ligand and Au(I) complexes (**38-50**).

^{13}C (MAS) solid state NMR for all complexes showed significant downfield shifts (6-11 ppm) for all carbon bonded to gold atom ($\text{Au}=\text{C}$) and up-field shift (~ 8 ppm) for all carbon bonding to selenium atom ($\text{C}=\text{Se}$). This attributed to back donation from gold to Se atom and indicating all complexes formed through binding to the selenium atom of the ligand. These phenomena were also observed in sulfur gold(I) complexes [102]. For all complexes, solid and liquid state chemical shift were consistent indicating the stability of the synthesized complexes in solid and liquid states. ^{13}C (MAS) NMR Chemical shifts of complexes (**38-50**) are given in Table 4.4.

^{77}Se NMR chemical shift in all complexes is more shielded than that of free ligands. This phenomenon is attributed to ($\text{Au}\rightarrow\text{Se}=\text{C}$) back bonding and the transferred electron density of $\text{N}\rightarrow\text{C}$ resulting a partial double character in $\text{C}-\text{N}$ bond which confirms the coordination is done through binding to the selenium atom [105]. ^{77}Se NMR studies showed that DiapSe and DiazSe and their derivatives ligate more strongly than ImSe along with their derivatives. The selenol form be as a higher contribution for DaipSe and DaizSe relatively to ImSe due to ring strain hindering the rehybridization of N culminating in DaipSe as shown in Table 4.5. A linear correlation between ^{13}C NMR chemical shifts of $^{13}\text{C}=\text{Se}$ and ^{77}Se NMR chemical shift of complexes (**40,41, 43-45** and **49**) due to decrease ring constrain is shown in Figure 4.1.

Figure 4.1. Plot of $^{13}\text{C}=\text{Se}$ NMR chemical shift against observed ^{77}Se chemical shifts for complexes (40, 41, 43-45, and 49).

Table 4.3. ^{13}C NMR chemical shifts (ppm) for free ligands and gold(I) complexes (**38-50**) in CDCl_3 .

4.3.2 Single crystal X-ray structure determination

X-ray data of **39**, **44**, **46**, **48** and **49** were collected on a Stoe Mark IPD-2 System [163] with a two-circle goniometer and using MoK α graphite monochromator. The distance between the imaging plate and the sample was 100 mm. Structures were solved using the program SHELXS-97 [164]. The non-H atoms were refined using least-squares matrix on F². Crystal data and refinement details for complexes **39** and **49** are given in Table 4.8. The structures of these complexes were drawn using the programs PLATON and MERCURY [130].

The molecular structure of complex [Au(Ipr)(SeCN₂C₄H₁₀)]⁺ (**39**) is depicted in Figure 4.2. Selected bond lengths and angles are given in Table 4.6. The coordination geometry around the gold ion is close to linearity, with (C—Au—Se) 176.8(7)°. The Au—C and Au—Se bond lengths are 2.40(4) and 2.00(2) Å, respectively. The bond lengths and bond angle are similar to those reported for other compounds [165].

Figure 4.2. Molecular structure of complex **39**, with partial labelling atoms and 50% probability ellipsoids.

Table 4.6. Selected bond lengths and bond angles for complex **39**.

Bond Length (Å)		Bond Angles (°)	
Au ₁ —Se ₁	2.40 (4)	Se ₁ —Au ₁ —C ₆	176.8 (7)
Au ₁ —C ₆	2.00 (2)	Au ₁ —Se ₁ —C ₁	98.62 (8)

The molecular structures of complexes **44**, **46** and **48** are shown in Figures 4.3, 4.4 and 4.5 respectively.

Figure 4.3. Molecular structure of complex $[\text{Au}(\text{Ipr})(\text{SeCN}_2\text{H}_4)]\text{PF}_6$ (**44**), with partial labelling atoms and 50% probability ellipsoids.

Figure 4.4. Molecular structure of complex $[\text{Au}(\text{Ipr})(\text{SeCN}_2\text{C}_4\text{H}_{10})]\text{PF}_6$ (46), with partial labelling atoms and 50% probability ellipsoids.

Figure 4.5. Molecular structure of complex $[Au(Ipr)(SCN_2C_2H_8)]PF_6$ (**48**), with partial labelling atoms and 50% probability ellipsoids.

The molecular structure of complex $[Au(Ipr)(SeCN_2C_5H_{12})]PF_6$ (**49**) is shown in Figure 4.6. Selected bond lengths and angles are illustrated in Table 4.7. The geometry of the coordination around gold ion formed by carbon of NHC ligand and Selenium ligand, is close to linearity, with (C—Au—Se) angle of $177.1(5)^\circ$. The Au—C and Au—Se bond lengths are 2.11(2) and 2.38(3) Å, respectively. The bond lengths and bond angles are similar to those reported for other compounds [166].

Figure 4.6. Molecular structure of complex 49, with partial labelling atoms and 50% probability ellipsoids. The hydrogen atoms have been omitted for clarity.

4.3.3 In vitro cytotoxic activities of gold(I) complexes (38-50)

Gold(I) complexes labeled (38-50) were tested for *in vitro* cytotoxicity against A549 (human lung carcinoma), MCF7 (human breast adenocarcinoma) and HCT15 human cancer cell lines (human colon cancer) using MTT assay and compared with *cisplatin* (standard anticancer drug). IC₅₀ values (μM) of complexes (38-50) against HCT15, A549 and MCF7 cancer cell lines are shown in Table 4.9.

The dose-dependent inhibition of cell proliferation was obtained by specific increase of *cisplatin* and complexes (38-50) concentrations against a fixed number of three human cancer cell lines Figures 4.7(a, b and c)- 4.9(a, b and c). IC₅₀ values were obtained from the curve of the concentration of *cisplatin*, and complexes (38-50) against percentage of cell viability. For HCT15 cell line, the IC₅₀ values for complexes (38-50) are in the range of (54 ± 1— 51 ± 2 μM), respectively, compared to *cisplatin* 32 ± 2 μM. The data showed the complex 48 (28 ± 2 μM) has inhibition of cell proliferation and potency levels better than that exhibited by *cisplatin* (32. ± 2 μM), suggesting S containing ligand is more labile than Se containing ligand and enhanced the cytotoxic activity of this complex Au(Ipr)(SCN₂C₂H₈)]PF₆. The complex 45 (33 ± 1 μM) has similar IC₅₀ value to *cisplatin*. However, for A549 and MCF7 cell lines, complexes (38-50) exhibited moderate to higher IC₅₀ values with respect to *cisplatin*.

Table 4.9. IC₅₀ values (μM) of gold(I) complexes (**38-50**) against HCT15, A549 and MCF7 cancer cell lines.

Complex	HCT15	A549	MCF7
Cisplatin	32 ± 2	42 ± 2	23 ± 4
38	54 ± 1	62 ± 2	60 ± 2

CHAPTER 5

SYNTHESIS AND CHARACTERIZATION OF (TRI-TERT-BUTYLPHOSPHINO)GOLD(I)THIONE COMPLEXES

5.1 Introduction

Auranofin is a linear Au(I) complex of triethyl phosphine and tetracetylthiogulucose ligands, which has been used as anti-arthritis drug. Later in 1980s it was investigated clinically as anticancer drug in mice [166]. A series of analogues, mainly Au(I) phosphine complexes showed promising *in vitro* and *in vivo* anticancer tests [167-169]. Recently, studies on gold complexes with phosphine and sulfur donor ligands in cancer chemotherapy are growing rapidly. Some water soluble gold(I) phosphine derivatives have tested against *in vitro* and *in vivo* against colon cancer [170]. Zou et al. reviewed the biochemistry of Au(I) and Au(III) complexes and demonstrated their mechanism of action [124].

5.2 Experimental Section

5.2.1 Materials and instrumentation

All solvents were of analytical grade, used without further purification. Ethanol, diethyl ether, dichloromethane, acetone, were purchased from Fluka AG (St. Gallen, Switzerland). Chloro(tri-tert-butylphosphine)gold(I) complex from Stream Chemicals Inc. (Newburyport, Massachusetts, United States). AgPF_6 was purchased from Sigma-Aldrich, United States. 1,3-diazinane-2-thione (Diaz), N-hydroxyethyl, 1,3-imidazolidine-2-thione (2-EtOH-Imt), 1,3-diazepine-2-thione (Diap) and N-ethyl-1,3-diazinane-2-thione (N-Et-Diaz) were prepared as reported [171]. ^1H , ^{13}C , ^{31}P NMR, FT-IR spectroscopy and elemental analyses were described in section 3.1.

5.2.2 Synthesis of (tri-tert-butylphosphino)gold(I) thione complexes (52-55)

Scheme 22. Synthesis of (tri-tert-butylphosphino)gold(I) with thione complexes (**52-55**).

[Au{P(t-Bu)₃}(SN₂C₃H₆)]PF₆ (52**)**

AgPF₆ (0.127 g, 0.500 mmol) was dissolved in 7 mL of ethanol and then added to a solution of (t-Bu)₃PAuCl (0.217 g, 0.500 mmol) in acetone (7 mL). The resulting mixture was stirred at ambient temperature for 30 mins. and filtered off. 1, 3-diazinane-2-thione (0.058 g, 0.50 mmol) was then added to the filtrate, the mixture was stirred for 2 hours, filtered and stored in undisturbed area. After four days bright yellowish-white crystals were obtained and a suitable crystal was selected for single crystal diffraction analysis. Yield 0.268 g (81%). Anal. calc. for C₁₆H₃₅AuN₂P₂SF₆ (660.43 g/mol): C, 29.09; H, 5.34; N, 4.24; S 4.85. Found: C, 31.26; H, 3.99; N 3.01; S 3.03.

[Au{P(t-Bu)₃}(SN₂C₅H₉-OH)]PF₆ (53**)**

Complex **53** was prepared using N-hydroxyethyl-1,3-imidazolidine-2-thione (0.073 g, 0.50 mmol) by a procedure similar to (**52**). After three days a colorless solid was obtained.

Yield 0.213 g (62%). Anal. calc. for $C_{17}H_{37}AuN_2OP_2SF_6$ (690.46 g/mol): C, 29.57; H, 5.40; N, 4.05; S, 4.64. Found: C, 30.39; H, 4.52; N, 4.13; S, 4.55.

[Au{P(t-Bu)₃}(SN₂C₅H₁₀)PF₆ (54**)**

Complex **54** was prepared using 1,3-diazepine-2-thione (0.065 g, 0.50 mmol) by a procedure similar to (**52**). After three days the colorless crystals were obtained. A suitable crystal was selected for single crystal diffraction analysis. Yield 0.192 g (57%). Anal. Calc. for $C_{17}H_{37}AuN_2P_2SF_6$ (674.46 g/mol): C, 30.27; H, 5.52; N, 4.15; S, 4.75. Found: C, 30.91; H, 4.16; N, 4.70; S, 4.94.

[Au{P(t-Bu)₃}(SN₂C₅H₁₀)PF₆ (55**)**

Complex **55** was prepared using N-ethyl-1,3-diazinane-2-thione (0.072 g, 0.50 mmol) by a procedure similar to (**52**). After three days the yellow crystals were obtained. A suitable crystal was selected for X-ray diffraction analysis. Yield 0.213 g, (62 %). Anal. Calc. for $C_{18}H_{39}AuN_2P_2SF_6$ (688.49 g/mol): C, 31.40; H, 5.70; N, 4.06; S, 4.65. Found: C, 31.52; H, 4.24; N, 4.57; S, 4.97.

5.3 Results and discussion

5.3.1 Spectroscopic characterization

The synthesized chloro(tri-tert-butylphosphino)gold(I) with thione complexes (**52-55**) are shown in (Scheme 22) and were characterized by ¹H, ¹³C and ³¹P NMR and mid FT-IR spectroscopy, elemental analyses and single crystal X-ray diffraction analysis. The mid

FT-IR spectroscopy data of free ligands and complexes (**52-55**) are summarized in Table 5.1.

The formation of complexes (**52-55**) was confirmed by the significant shift in frequencies of free ligands to their complexes. For instance, $\nu(\text{C}=\text{S})$ band in free ligands is in the range of (1001-1191 cm^{-1}), however for complexes (**52-55**) it is in the range of (830-875 cm^{-1}) due to C=S weaken upon coordination [133]. In the complexes (**52-55**) the strong $\nu(\text{C}-\text{N}=\text{S})$ absorbance bands were assigned in the range (1443-1480) cm^{-1} due to increasing double character in C-N bond.

Table 5.1. Mid FT-IR frequencies (cm^{-1}) of free ligand and (tri-tert-butylphosphino)gol(I) thione complexes (**52-55**).

Ligand/ Complex	Stretch NH/OH					Stretch N—C	Stretch C=S
Diaz	-	-	-	2924	1360	1488	1066
2EtOHImt	-	2979	1379	2925	1358	1466	1065
Diap	-	-	-	2922	1347	1445	1001
EtDiaz	-	-	-	2935	1315	1448	1191
52	3402 (NH)	3000	1370	2954, 2870	1319	1480	875
53	3600 (OH)	2999	1368	2953, 2895	1328	1476	830
54	3379 (NH)	3005	1370	2952, 2861	1223	1480	846
55	3409 (NH)	2952	1375	2904, 2870	1258	1443	852

The comparison of the ^1H NMR spectra of free thione ligands and their complexes (**52-55**) showed significant shifts that indicate complexation. For example, ^1H NMR data for the complex **52** display a doublet at 1.48 ppm, triplet at 3.23 ppm, and triplet at 1.77 ppm while $t\text{-Bu}_3\text{PAuCl}$ shows a doublet at 1.51 ppm as shown in Table 5.2.

Table 5.2. ^1H NMR chemical shifts (ppm) for free ligands and (tri-tert-butylphosphino) gold(I) thione complexes (51-55) in DMSO.

55	1.47 d	3.21 t	1.86 m	3.44 t	3.77 q	1.17 t	8.97	-

The chemical shifts of ^{13}C and ^{31}P NMR for free ligand and their Au(I) compounds (**51-55**) are shown in Table 5.3.

^{13}C NMR spectra support the proposed structure of the synthesized complexes. The C=S resonance shifted to upfield in all complexes by 4-7 ppm most likely due to back donation from gold ion to the π^* C=S [171-172]. The C4 (C—N) resonance was shifted downfield in all complexes relatively to the free ligand likely due to the increase of sp² character of nitrogen upon coordination.

^{31}P NMR spectra are in agreement with ^1H and ^{13}C NMR results. The ^{31}P resonance appears at -10.69 ppm for t-Bu₃PAuCl, thus being shifted downfield upon coordination in all complexes. A linear correlation between ^{31}P NMR chemical shift and $^{13}\text{C}=\text{S}$ NMR chemical shifts due to increase ring constrain of complexes (**52-55**) is shown in Figure 5.1.

Figure 5.1. Plot of ^{31}P NMR chemical shift against observed $^{13}\text{C}=\text{S}$ NMR chemical shift for complexes (52-55).

Table 5.3. ^{13}C and ^{31}P NMR chemical shifts (ppm) for free ligands and (tri-tert-butylphosphino)gold(I) thione complexes (51-55) in DMSO.

5.3.2 Signal crystal X-ray structure determination

The structures of complexes **54** and **55** were determined at 173 K (−100 °C) using a STOE IPDS 2 with a two-circle goniometer and MoK α graphite monochromator [127]. Diffraction data collected using a detector image plate (34 diameter) and sealed X-ray tube diffraction source 12 x 0.4 mm long fine-focus. The structures were solved using the programs SHEXLX97, SHELXS-2014 [173]. The non-hydrogen atoms were refined using least-squares matrix on F². The structure of complex **54** and **55** were drawn using the programs PLATON and MERCURY [174]. A summary of crystal data and refinement details for complexes **54** and **55** are given in Table 5.6.

The molecular structure and crystal packing of compound $[Au\{P(t-Bu)_3\}(SN_2C_5H_{10})PF_6]$ (**54**) are shown in Figures 5.2 and 5.3 respectively. The selected bond lengths and bond angles for complex **54** is shown in Table 5.4.

The coordination geometry around gold ion with is close to linearity, with (P1—Au—S1) 178.1(7)°. The Au1—P1 and Au1—S1 bond lengths are 2.23(2) and 2.27(2) Å, respectively. The bond lengths and bond angle are similar to those reported for other compounds [126, 175].

The molecular structure and crystal packing of complex $[Au\{P(t-Bu)_3\}(SN_2C_5H_{10})PF_6]$ (**55**) are shown in Figures 5.4 and 5.5 respectively. The selected bond lengths and bond angles for complex **54** are shown in Table 5.5.

The coordination geometry around gold ion is close to linearity, with (P1—Au—S1) 178.0(5)°. The Au1—P1 and Au1—S1 bond lengths are 2.32(1) and 2.29(1)Å,

respectively. These bond lengths and bond angle are similar to those reported for analogous compounds [140-141].

CHAPTER 6

SYNTHESIS AND CHARACTERIZATION OF GOLD(I) CARBENE COMPLEXES WITH MONO AND BIS-PHOSPHINE LIGANDS

6.1 Introduction

N-heterocyclic carbene (NHC) is versatile ligand with unique properties. Their metal complexes have potential applications in the field of medicinal inorganic chemistry and industry are currently a focus of the interest [119-121, 176]. Horvath et al. prepared a series of gold(I) N-heterocyclic carbene complexes with bisphosphine ligands and evaluated for their *in vitro* and *in vivo* anticancer activity [177].

6.2 Experimental Section

6.2.1 Materials and Instrumentation

All solvents were of analytical grade and used without further purification. Ethanol, diethyl ether, dichloromethane, acetone, were purchased from Fluka AG (St. Gallen, Switzerland). 1,3-Bis(2,6-di isopropylphenyl)imidazol-2-ylidenechloridogold(I) [Au(Ipr)Cl], Bis(2-cyanoethyl)phenylphosphine, (1R,2R)-2-(diphenylphosphino)-1

-aminocyclohexane, (1R, 2R)-2-(diphenylphosphino)-1,2-diphenylethylamine, (R)-2-(diphenylphosphino)-1-phenylethylamine, (R)-1-(diphenylphosphino)-2-amino-3,3-dimethylbutane, tricyclohexylphosphine, 3-(diphenylphosphino)propylamine, 1,3-bis(Diphenylphosphino)propane, 1,2-bis(Diphenylphosphino)ethane and bis[2-(Dicyclohexyl(phosphino)ethyl)]amine were purchased from Stream Chemicals Inc. (Newburyport, Massachusetts. United States). AgPF₆ was purchased from Sigma-Aldrich, United States. ¹H, ¹³C, ³¹P NMR, FT-IR spectroscopy and elemental analysis were described in section 3.1.

6.2.2 Synthesis of gold(I) N-heterocyclic carbene with mono and bis-phosphine complexes (56-65)

Scheme 23. Synthesis of gold(I)-carbene with mono and bis-phosphine complexes (56-65).

Scheme 23. Synthesis of gold(I)-carbene with mono and bis-phosphine complexes (56-65).

Scheme 23. Synthesis of gold(I)-carbene with mono and bis-phosphine complexes (56-65).

[Au(Ipr)(C₁₂H₁₃N₂P)]PF₆ (56**)**

AgPF₆ (0.127 g, 0.500 mmol) was dissolved in 5 mL of ethanol was added to a solution of 1,3-Bis(2,6-diisopropylphenyl)imidazol-2-ylidenechloridogold(I) [Au(Ipr)Cl] (0.311 g, 0.500 mmol) in acetone (5 mL). The resulting mixture was stirred at ambient temperature for 10 min and then the mixture was filtered off. Bis(2-cyanoethyl) phenylphosphine (0.108 g, 0.500 mmol) was added to the filtrate, stirred for 30 min, filtered and stored in undisturbed area. After five days colorless crystals were obtained and a suitable crystal was selected for X-ray diffraction analysis. Yield 0.313 g (66%). Anal. calc. for C₃₉H₄₉AuN₄P₂F₆ (946.75 g/mol): C, 49.42; H, 5.31; N, 5.91. Found: C, 55.28; H, 5.31; N, 6.73.

[Au(Ipr)(C₁₈H₂₂NP)]PF₆ (57**)**

Complex **57** was prepared using (1R,2R)-2-(diphenylphosphino)-1-aminocyclohexane (0.142 g, 0.500 mmol) following a procedure similar to (**56**). After three days a colorless solid was obtained. Yield 0.344 g (68%). Anal. calc. for C₄₅H₅₉AuN₃P₂F₆ (1014.87 g/mol): C, 49.42; H, 5.31; N, 4.14. Found: C, 53.61; H, 6.06; N, 4.15

[Au(Ipr)(C₂₆H₂₄NP)]PF₆ (58**)**

Complex **58** was prepared using (1R,2R)-2-(diphenylphosphino)-1,2-diphenylethylamine (0.159 g, 0.500 mmol) following a procedure similar to (**56**). After five days a yellow solid was obtained. Yield 0.363 g (65%). Anal. calc. for C₅₃H₆₁AuN₃P₂F₆ (1112.98 g/mol): C, 57.19; H, 5.52; N, 3.77. Found: C, 56.08; H, 5.93; N, 3.79.

[Au(Ipr)(C₂₀H₂₀NP)]PF₆ (59**)**

Complex **59** was prepared using (R)-2-(diphenylphosphino)-1-phenylethylamine (0.153 g, 0.500 mmol) following steps similar to (**56**). After five days a yellow solid was obtained. Yield 0.402 g (78%). Anal. calc. for C₅₃H₆₁AuN₃P₂F₆ (1036.88 g/mol): C, 54.44; H, 5.54; N, 4.05. Found: C, 53.47; H, 5.93; N, 3.99.

[Au(Ipr)(C₁₈H₂₄NP)]PF₆ (60**)**

Complex **60** was prepared using (R)-1-(diphenylphosphino)-2-amino-3,3-dimethylbutane (0.143 g, 0.500 mmol) following a procedure similar to (**56**). After four days a colorless solid was obtained. Yield 0.357 g (77%). Anal. calc. for C₃₉H₄₉AuN₃P₂F₆ (932.73 g/mol): C, 50.22; H, 5.29; N, 4.50. Found: C, 45.96; H, 5.80; N, 3.72.

[Au(Ipr)(C₁₈H₃₃P)]PF₆ (61**)**

Complex **61** was prepared using tricyclohexyl-phosphine (0.140 g, 0.50 mmol) by a procedure similar to (**56**). After five days colorless solid was obtained. Yield 0.411 g (81%). Anal. calc. for C₄₅H₆₉AuN₂P₂F₆ (1010.95 g/mol): C, 53.46; H, 6.87; N, 2.77. Found: C, 56.42; H, 8.34; N, 3.02

[Au(Ipr)(C₁₅H₁₈NP)]PF₆ (62**)**

Complex **62** was prepared using 3-(diphenyl- phosphino)propylamine (0.122 g, 0.5 mmol) following a procedure similar to (**56**). After three days a colorless solid was obtained. Yield 0.310 g (64%). Anal. calc. for C₄₂H₅₄AuN₃P₂F₆ (973.80 g/mol): C, 51.80; H, 5.58; N, 4.31. Found: C, 52.68; H, 6.48; N, 4.54.

$[(\text{Au}(\text{Ipr}))_2(\text{C}_{27}\text{H}_{26}\text{P}_2)](\text{PF}_6)_2$ (63)

AgPF_6 (0.127 g, 0.500 mmol) was dissolved in 5 mL of ethanol and the solution was added to a solution of 1,3-Bis(2,6-di-isopropylphenyl)imidazol-2-ylidenegoldchlorido(I) $[\text{Au}(\text{Ipr})\text{Cl}]$ (0.311 g, 0.500 mmol) in dichloromethane 5 mL. The resultant mixture was stirred at ambient temperature for 10 min and then filtered off. 1,3-Bis(Diphenylphosphino)propane (0.103 g, 0.250 mmol) in dichloromethane 5 mL was added to the filtrate. The mixture stirred for 30 min, filtered and the filtrate stored in a undisturbed area. After five days the colorless crystals were obtained and a suitable crystal was selected for X-ray diffraction analysis. Yield 0.332 g, (71%). Anal. Calc. for $\text{C}_{81}\text{H}_{98}\text{Au}_2\text{N}_4\text{P}_4\text{F}_{12}$ (1873.48 g/mol): C, 51.92; H, 5.27; N, 2.99. Found: C, 44.85; H, 5.04; N, 3.02.

$[(\text{Au}(\text{Ipr}))_2(\text{C}_{26}\text{H}_{24}\text{P}_2)](\text{PF}_6)_2$ (64)

Complex **64** was prepared using 1,2-Bis(Diphenylphosphino)ethane (0.100 g, 0.250 mmol) by a procedure similar to **(63)**. After five days a colorless solid was obtained. Yield 0.308 g, (66 %). Anal. Calc. for $\text{C}_{80}\text{H}_{96}\text{Au}_2\text{N}_4\text{P}_4\text{F}_{12}$ (1873.48 g/mol): C, 51.67; H, 5.20; N, 3.01. Found: C, 56.42; H, 6.22; N, 3.32.

$[(\text{Au}(\text{Ipr}))_2(\text{C}_{28}\text{H}_{24}\text{P}_2)](\text{PF}_6)_2$ (65)

Complex **65** was prepared using Bis[2-(Dicyclohexylphosphino)ethyl]amine (0.117 g, 0.250 mmol) by a procedure similar to **(63)**. After five days the colorless crystals were obtained and a suitable crystal was selected for X-ray diffraction analysis. Yield 0.290 g

(60%). Anal. calc. for $C_{82}H_{125}Au_2N_5P_4F_{12}$ (1926.71 g/mol): C, 51.11; H, 6.53; N, 3.63. Found: C, 50.68; H, 6.52; N, 3.45.

6.3 Results and Discussion

6.3.1 Spectroscopic Characterization

The ligands (**L3-L12**) and their gold(I) complexes (**56-65**) were synthesized (Scheme 23) and were characterized using by 1H , ^{13}C and ^{31}P NMR and mid FT-IR spectroscopy, elemental analyses and single crystal X-ray diffraction analysis.

The FT-IR frequencies for free ligand and their complexes (**56-65**) are shown in Table 6.1. FT-IR spectra showed weak absorbance in the region of ($3049-3078\text{ cm}^{-1}$) assigned to benzene ring $=C-H$ stretching for the free ligands and precursor **38**. This absorbance was shifted to higher frequency in the range ($3120-3175\text{ cm}^{-1}$) in all complexes. The $\nu(C\equiv N)$ band for free ligand **L2** appears at 2250 cm^{-1} and for it is complex **56** was shifted lower frequency at 2242 cm^{-1} this significant shift support complexation.

Table 6.1. Mid FT-IR frequencies (cm⁻¹) of gold(I) with mixed carbene and phosphine complexes (**56-65**).

The ^1H NMR chemical shifts of free ligands and their complexes (**56-65**) are given in Table 6.2. ^1H NMR data showed significant shift in carbene moiety between precursor **38** and their complexes (**56-65**). ^1H NMR chemical shift of NH in free ligands (**L2-L5** and **L7**) was observed in the range (1.09-2.02 ppm) and shifted downfield for their complexes (**57-60** and **62**) in range (1.17-2.21 ppm). For all free ligands, ^1H MNR data of H—C—P moiety observed downfield to their complexes due to back donation from gold ion to π^* P—C bond.

^{13}C NMR chemical shifts for free ligands and their complexes are summarized in Table 6.3. ^{13}C NMR chemical shift (C=Au) for precursor **38** was observed at 175.3 ppm. whereas, for their complexes was shifted downfield in the range (187.9-207.2 ppm) likely due to weaker back bonding from gold ion to π^* P—C bond.

.

³¹P NMR chemical shifts (ppm) for free ligands and gold(I) complexes (**56-65**) are given in Table 6.4. The resonance values for free ligands are in the range (-25.14— -9.22 ppm), whereas those of their complexes were observed downfield in the range (30.26—46.46 ppm) due to back donation from gold ion to π^* P—C bond. Expect for **L8** appearing at 9.33 ppm and complex **61** observed upfield at -44.54.

6.3.2 Signal crystal X-ray structure

The structure of complexes **56**, **61**, **63** and **65** were determined using STOE IPDS 2 system at 203-293K with a two-circle goniometer and MoK α graphite monochromatic radiation[127]. Structures were solved using the program SHELXS-97 [178-180]. The non-hydrogen atoms were refined using least-squares matrix on F². The molecular structures of complexes are consistent with spectroscopic data and are illustrated in Figures (6.1—6.4). The coordination geometry around gold(I) ion is distorted from linearity with angle (C—Au—P) of 177.0(4)°, 179.9(3)°, (173.1(6) and 174.4(6)° [181]. The bond lengths and bond angles for complexes **56**, **61** and **63** are illustrated in Tables 6.5, 6.7 and 6.9. Summary of crystal data and details of the structure refinement for complex (**56**, **63** and **65**) are shown in Tables 6.6, 6.8 and 6.10.

The pronounced distortion in compound **63** (173.1(6). The C—Au and Au—P bond lengths (Å) are 2.052(14); 2.022 (11); 2.060(2) and 2.261(5); 2.295(3); 2.280(6) are similar to those reported [182].

The hydrogen-bond (Å) for complex **61** is found to be PF₆⁻---H—CCl₃ between (F1) of counter ion (PF₆⁻) and hydrogen of (CHCl₃) as solvent. The hydrogen bond length (Å) and bond angle (°) are H---F1 2.25(5) and C—H---F1 is 170°, respectively.

CHAPTER 7

SPECTROSCOPIC STUDIES OF INTERACTIONS OF THE POTENTIAL ANTICANCER AGENTS $[\text{Au}(\textit{cis}\text{-DACH})\text{Cl}_2]\text{Cl}$ AND $[\text{Au}(\textit{cis}\text{-DACH})_2]\text{Cl}_3$ WITH BIOLOGICALLY RELEVANT THIONES

7.1 Introduction.

The study of metallo-drugs, containing sulfur donor ligands, with interesting physical, chemical, biological and pharmacological properties have attracted attention [183-184]. Among these, gold complexes are a new class of metal-based drugs with promising potential antitumor properties [23]. Notably, a number of gold(I) and gold(III) complexes are reported to possess cytotoxic effects against selected human cancer cell lines [185], gold(I)-thiolates as anti-arthritis [186-187] and antitumor drugs [8,138,188]. In contrast, the pharmacological behavior of gold(III) derivatives containing thiols and thiones is unclear and is an underdeveloped field in modern inorganic chemistry [133]. These compounds have the ability to form uranophilic bond [49-50]. Gold(III) is isoelectronic

and square planar structure similar to Pt(II), and the interaction of their complexes with thiols and thiones have been widely reported [189].

Ghosh et al. studied kinetics of the interaction of Pd(II) imidazole derivative and 2-aminopyrimidine and they concluded their study with a proposed mechanism [190]. Moreover, the kinetic and mechanistic studies were carried out for the interaction of *cis*-[Pt(en)(H₂O)₂](ClO₄)₂ and *cis*-[Pt(dmen)(H₂O)₂](ClO₄)₂, where en = ethylenediamine and dmen = *N,N*-dimethyl-ethylenediamine, with glycine under pseudo first-order conditions as a function of temperature, pH and ligand concentration [191]. Ray et al. evaluated activation parameters of kinetics for the substitution reactions of *cis*[Pt(*cis*-DACH)(H₂O)₂]²⁺, DACH=1,2-diaminocyclohexane, with dipeptides containing glycine, glutathione and penicillamine under pseudo first-order conditions dependent on pH, ligand [192].

The oxidation of thiols and thioether groups that are part of amino acids, via metal ions, has been investigated for decades due to their important role in function and structure of proteins [193]. The interaction of [Au(CN)₄]⁻, [Au(terpy)Cl]²⁺, [Au(bpma)Cl]²⁺, [Au(dien)Cl]²⁺ and [AuCl₄]⁻, where terpy = 2,2', 6', 2''-terpyridine, bpma = bis(pyridyl methyl)amine, dien = diethylene-triamine, with the biologically relevant thiols and thioether, such as L-Cysteine, glutathione and L-methionine, has been studied [106,194]. These studies were conducted by cyclic voltammetry (CV), ESI-MS, ¹H NMR and UV-Vis spectroscopy. In addition, researchers extensively studied kinetics and mechanism of redox reactions of Au(I) and Au(III) complexes to investigate their ligand exchange reactions and metabolism [195-196]. The kinetics of the formation and equilibrium hydrolysis of [AuBr₄]⁻ and [AuCl₄]⁻ have been studied and found to follow

a two-term rate law [197]. The study showed that their hydrolysis are faster than the analogous Pt(II) complexes.

The preparation and characterization of new gold(III) compounds with DACH was reported [198], the effect of stereochemistry of DACH on tumor activity, and the *cis*-DACH isomer showed the highest activity against human cancer cell lines such as prostate cancer (PC-3) and gastric carcinoma (SGC-7901). We report the interaction of $[\text{Au}(\textit{cis}\text{-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\textit{cis}\text{-DACH})_2]\text{Cl}_3$ with enriched thiourea (Tu) and 1,3-diazinane-2-thione (DIAZ) by ^1H , ^{13}C and ^{15}N NMR spectroscopy, UV-Vis spectroscopy, and electrochemistry. We also present the kinetics of these interactions.

7.2 Experimental Section

7.2.1 Materials and Instrumentation

$\text{NaAuCl}_4 \cdot 2\text{H}_2\text{O}$ and *cis*-DACH were purchased from Sigma-Aldrich, USA; absolute EtOH from Merck, D_2O from Alfa-Aesar, and thiourea from Cambridge Isotope Lab. Inc. DIAZ was prepared as described [171]. Deionized water with a resistivity of $18.6 \text{ M}\Omega \text{ cm}^{-1}$ was used to prepare all solutions. It was obtained directly from a PURELABs Ultra Laboratory Water Purification System.

7.2.2 Spectroscopic techniques

^1H NMR spectra were recorded on a JEOL-LA 500 MHz NMR spectrophotometer. The spectral conditions were: 32k data point, 3.2 s acquisition time, and 5.75 μs pulse width. ^{13}C NMR measurements were recorded at 125.65 MHz with ^1H broadband decoupling. The spectral conditions were: 32k point data, 1s acquisition time, 2.5s pulse delay, and

5.12 μ s pulse width. ^{15}N NMR spectra were recorded at 50.53 MHz with benzamide as external reference (932.56 ppm) relative to internal reference NH_4NO_3 (375.11 ppm). All spectra were recorded at 297 K in D_2O using tetramethylsilane (TMS) as internal standard.

7.2.3 Electrochemical technique

A CHI660 potentiostat was used for all square wave stripping voltammetric (SWSV) measurements. The electrochemical cell contained a glassy carbon electrode (GCE; 3.0 mm diameter, Model CHI104, CH Instruments, Austin, TX) as a working electrode, Ag/AgCl (sat. KCl) reference electrode (Model CHI111, CH Instruments, Austin, TX), and a platinum wire counter-electrode were inserted into a 2-mL glass cell through holes in its Teflon cover. Prior to each SWSV measurement, the GCE was polished with 3.0 and 0.05 μm alumina slurries and washed with double-distilled water. Each SWSV measurement was performed at room temperature in a quiescent 0.2 M KCl aqueous solution, and with an initial potential of 0.0V and final potential of +1.6V.

7.2.4 Synthesis of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$

$[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ was synthesized as described in the literature [199]. $\lambda_{\text{max}} = 305$ nm. ^1H NMR, ppm, δ : 3.59 m, 2.02 m, 1.76 m, 1.47 m, and 1.29 m. ^{13}C NMR, ppm, δ : 63.3, 26.8, and 21.4. Anal. Found (calculated) for $\text{C}_6\text{H}_{14}\text{AuCl}_3\text{N}_2$ (417.51 g/mol): C, 17.22 (17.26); H, 3.38 (3.35); N, 6.67 (6.71).

7.2.5 Synthesis of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$

[Au(*cis*-DACH)₂]Cl₃ was synthesized as described in the literature [199]. $\lambda_{\text{max}} = 344$ nm. ¹H NMR, ppm, δ : 3.58 m, 1.94 m, 1.74 m, 1.54 m, 1.38 m. ¹³C NMR, ppm, δ : 61.7, 61.6, 26.3, 26.1 and 20.6. Anal. Found (calculated) for C₁₂H₂₈AuCl₃N₄ (531.70 g/mol): C, 27.02 (27.11); H, 5.28 (5.31); N, 10.61 (10.54).

7.2.6 Kinetic Measurements

The kinetic measurements were carried out on a Cary 100 UV-Vis spectrophotometer (Agilent Technologies) connected with a Cary temperature controller (accuracy = ± 0.1 °C). The working wavelengths were determined over the wavelength range (200 -500 nm) (Fig. 7.11). The reactions were started by mixing the complex in 30 mM KCl solution and ligand solutions in equal volumes directly in a vial kept inside the instrument. The kinetic measurements were made under pseudo first-order conditions, where concentration of the complex is 0.2 mM with excess ligands (2-10 mM). The reactions were carried out at different temperatures of 288.2, 298.2 and 310.2 K. The pseudo first-order rate constant k_{obsd} was calculated as an average value of seven independent kinetic runs. All calculations were maintained using Microsoft Excel, Origin 8.

7.3 Results and Discussion

7.3.1 Interaction of [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ with enriched Tu and DIAZ

Interactions of [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ with enriched 10 % Tu (¹³C,¹⁵N) and DIAZ were carried out in D₂O using different concentrations of Tu and

DIAZ. The reaction products were monitored by ^1H , ^{13}C and ^{15}N NMR, UV-Vis spectroscopy and electrochemistry. The interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu was monitored by ^{13}C NMR as shown in (Fig. 7.1). Fig. 7.1a shows the ^{13}C NMR spectrum of 1 mg Tu (^{13}C enriched), and Fig. 1b shows the ^{13}C NMR spectrum of the oxidation reaction of Tu by H_2O_2 , which resulted in the formation of urea $(\text{NH}_2)_2\text{CO}$ and Tu dioxide, $(\text{NH}_2)_2\text{CO}_2\text{S}$ [200-201]. When enriched Tu (0.25 eq.) was added to 1 eq. of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$, their solution changed to yellow colour (Fig. 7.1A-c) and the ^{13}C NMR peak of enriched Tu was observed up-field at 179.68 ppm due to complexation, similar to previous observations [96]. Whereas, no peak was observed for $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at the same conditions. Figure 7.1A-d shows the formation of $[\text{Au}(\text{cis-DACH})\text{Tu}_2]^{3+}$ at 164.59 ppm, which is consistent with Fig. 7.1B-c of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at the same mole ratio (1: 0.5). Upon addition of enriched Tu to the solutions complex: Tu (1:1) and (1:4) of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ respectively, a colourless solution was observed with yellow precipitation due to the reduction of Au(III) to Au(I) [202], as shown in Fig.7.1(A-e), Fig. 7.1(A-f) and Fig. 7.1(B-d). The signal at 164.59 ppm remained constant and two new intense signals at 182.04 ppm and 184.87 ppm, which appeared as triple due to ^{15}N coupling [203-204]. The ^{13}C NMR chemical shifts of different species in the interaction progress are shown in Table 7.1.

Table 7.1. ^1H , ^{13}C NMR chemical shifts of the free ligand enriched (Tu), the $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (A) and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ (B) complexes in D_2O .

Figure 7.1. (A) ^{13}C NMR spectra for: free Tu (a), oxidation of Tu by H_2O_2 (b), the reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and Tu, 1:0.25 (c), at 1:0.5 (d), at 1:1 (e), and at 1: 4 (f). (B) ^{13}C NMR spectra for: free Tu (a), oxidation of Tu by H_2O_2 (b), the react of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu at 1:1(c), and at 1:4 (d). All spectra were recorded in D_2O .

^{15}N NMR spectrum of the reaction of enriched Tu (^{13}C , ^{15}N) with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (Fig. 7.2-A) shows a peak for free Tu at 583.26 ppm. An up-field shift to 409.17 ppm and 244.55 ppm at complex: Tu (1:1) and (1:2) mole ratio, respectively, indicates consecutive replacement of chloride. At complex: Tu (1:4 eq.), $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ was reduced to colourless $[\text{Au}(\text{Tu})_2]^+$, which was confirmed by a peak at 538.07 ppm [101]. Similarly, the reaction of the same ligand with $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ showed three peaks: 403.56 ppm at (1:1), as well as 277.15 ppm and 538.58 ppm at (1:2), which are indicative for the presence of $[\text{Au}(\text{cis-DACH})_2\text{Tu}]^{3+}$, $[\text{Au}(\text{cis-DACH})(\text{Tu})_2]^{3+}$ and $[\text{Au}(\text{Tu})_2]^+$, respectively (Fig. 7.2 B).

The substitution reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and Tu was studied by UV-Vis spectroscopy in aqueous solution containing 30 mM KCl at pH 3.5. Two bands at 390 nm and 249 nm, assigned to $[\text{Au}(\text{cis-DACH})(\text{Tu})\text{Cl}]^{2+}$ and $[\text{Au}(\text{cis-DACH})(\text{Tu})_2]^{3+}$, respectively, were observed, which are attributed to charge transfer from metal to ligand (M \rightarrow Tu). The bands at 237 nm and 230 nm represent a redox reaction, assigned to $[\text{Au}(\text{Tu})_2]^+$ Fig. 7.3 [101].

We then studied the interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu in aqueous solution containing 0.2 M KCl by square wave stripping voltammetry. Well-defined SWSV peaks are obtained at +0.82V and +1.35V (vs. Ag/AgCl) for 0.48 mM $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$, respectively (Fig. 7.4 and Fig. 7.5). The obtained peak disappeared with the subsequent additions of Tu as in Fig. 7.4 (c-g) and Fig. 7.4 (c-h). The electrochemical results are in agreement with the ^1H , ^{13}C and ^{15}N NMR, and UV-Vis spectroscopy and confirmed the suggested mechanism (scheme 23).

Fig. 7.6 shows SWSV voltammetry for different concentrations of Tu itself in 0.2 M KCl solution.

Figure 7.2. (A). ^{15}N NMR spectra of free Tu (a), after the reaction with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ at (1:1) (b), at (1:2) (c) and at (1:4) (d) (B). ^{15}N NMR spectra of free Tu (a), after the reaction with $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at (1:1) (b), at (1:2) (c) and at (1:4) (d) in D_2O .

Figure 7.3. UV-Vis spectra for: free Tu (0.1 mM) (a), after reaction with $[Au(cis-DACH)Cl_2]Cl$ (0.1 mM) (b), complex: Tu, 1:0.5 (c), (1:1) (d), (1:2) (e) and at (1:4) (f) in aqueous solutions containing 30 mM KCl at pH 3.5.

Figure 7.4. SWSV of free (a) and presence (b) of 0.48 mM of $[Au(cis-DACH)Cl_2]Cl$ in 0.2 M KCl solution. Subsequent additions of 0.24 mM Tu (c-g). Working conditions of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency, 15Hz.

Figure 7.5. SWSV of free (a) and presence (b) of 0.48 mM of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ in 0.2 M KCl solution. Subsequent additions of 0.24 mM Tu (c-h). Working condition of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency, 15 Hz.

Figure 7.6. SWSV of free (a) and presence (b) of 0.24 mM of Tu in 0.2 M KCl solution. Subsequent additions of 0.48 mM Tu (b-f) at pH 3.5. Working condition of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency 15 Hz and in aqueous solution.

We also monitored the interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with DIAZ by ^{13}C NMR in D_2O , as shown in Fig. 7.7. Fig. 7.7a shows the ^{13}C NMR spectrum of 5 mM of DIAZ, and Fig. 7.7b shows the ^{13}C NMR spectrum of oxidation of DIAZ ($\text{RN}_2\text{C}=\text{S}$) with H_2O_2 , which produces $\text{RN}_2\text{CSSCN}_2\text{R}$. Reaction of both complexes with equimolar of DIAZ resulted in an up-field shift to 164.82 ppm in the ^{13}C NMR (Fig. 7.7 A-c and Fig. 7.7 B-c). Their solutions changed from yellow to orange after 1 hr, and later turned to colourless with white precipitation due to initial reduction of Au(III) to Au(I) and then oxidation of DIAZ to $(\text{DIAZ})_2$ [147, 205]. When $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ reacted with 2 eq. of DIAZ (Fig. 7.7A-d and Fig. 7.7B-d, the chemical shift of (C=S) of DIAZ shifted down-field to 169.55 ppm, and the solutions changed to pale yellow with yellow precipitation. At higher concentration of DIAZ (4 eq.), the ^{13}C chemical shift of (C=S) shifted down-field to 172.32 ppm and 171.61 ppm, respectively, (Fig. 7.7A-c and Fig. 7.7B-c) in agreement with that reported [99]. The proof of total reduction of Au(III) specie to Au(I) is confirmed by disappearance of the solution color with yellowish white precipitation.

The evidence for the coordination sulphur of the thione ligand is provided by ^{13}C NMR spectroscopy. The chemical shifts of the complexes are provided in Table 7.2.

Figure 7.7. (A) ^{13}C NMR spectra for: free DIAZ (a), oxidation of DIAZ by H_2O_2 (b), reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and DIAZ at (1:1)(c), at (1:2) (d) and at (1:4) (e); (B) ^{13}C NMR spectra for: free DIAZ (a), oxidation of DIAZ by H_2O_2 (b), reaction $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ and DIAZ at (1:1) (c), at (1:2) (d) and at (1:4) (e) in D_2O .

Table 7.2. ^{13}C NMR chemical shifts of the free ligand (DIAZ) and the $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (A) and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ (B) complexes in D_2O .

[1: 4]	174.5	171.6	41.6, 40.7 40.1, 39.0	-	20.1, 19.1 19.6, 18.8	18.4	51.4	49.9	27.1	27.4	21.7	20.5

The ^{13}C chemical shift of C=S (C2) shifted up-field by 2.1-11.8 ppm in all of the complexes according to reduction of double bond character in (C=S) thione group. (C4,C4') and C(5) are shifted downfield by 0.44-0.88 ppm due to the increase in double bond character of C=N group [61]. The substitution reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and DIAZ was studied by UV-Vis spectroscopy. It was carried out in aqueous solution containing 30 mM KCl at pH 3.5. Fig. 7.8 shows the UV-Vis spectra of the substitution reaction followed by redox reaction. Two bands at 235 nm and 245 nm correspond to the products substitution reaction referred to $[\text{Au}(\text{cis-DACH})\text{Cl}(\text{DIAZ})]^{2+}$ and $[\text{Au}(\text{cis-DACH})(\text{DIAZ})_2]^{3+}$, respectively. They are due to back bonding from metal to ligand ($\text{M} \rightarrow \text{DIAZ}$). The band at 207 nm represents redox reaction product $[\text{Au}(\text{DIAZ})_2]^+$, which is due to reductive elimination through trans-effect [147].

Figure 7.8. UV-Vis spectra for: free DIAZ (0.1 mM) (a), $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (0.1 mM) (b), reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and DIAZ 1:0.5 (c), 1: 1 (d), 1:2 (e), and 1:4 (f). All reactions were performed in aqueous solution containing 30 mM KCl at pH 3.5.

We then studied the interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with DIAZ in aqueous solutions containing 0.2 M KCl by square wave stripping voltammetry. A well-defined SWSV peak is obtained at +0.82V (vs. Ag/AgCl) for 0.48 mM $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (Fig. 7.9). Whereas for $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ is obtained at +1.35V (Fig. 7.10). The obtained peak disappeared with the subsequent additions of DIAZ [Fig. 7.9(c-h)].

Fig. 7.11 includes different concentrations of DIAZ itself in the presence of 0.2 M KCl solution.

Figure 7.9. SWSV of free (a) and presence (b) of 0.48 mM of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ in 0.2 M KCl solution. Subsequent additions of 0.24 mM of DIAZ (c-h). Working conditions of the pulse width (increment), 4 mV, pulse height (amplitude), 25 mV, frequency, 15

Figure 7.10. SWSV of free (a) and presence (b) of 0.48 mM of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ in 0.2 M KCl solution. Subsequent additions of 0.24 mM DIAZ (c-h) at pH 3.5. Working condition of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency, 15Hz in aqueous solution.

Figure 7.11. SWSV of free (a) and presence (b) of 0.24 mM of DIAZ in 0.2 M KCl solution. Subsequent additions of 0.48 mM DIAZ (b-f) at pH 3.5. Working condition of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency, 15 Hz in aqueous solution.

7.3.2 Kinetic Data

The kinetics of substitution reactions of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu and DIAZ were studied by following the change of absorbance at selected λ_{max} . Pseudo first-order reaction conditions were employed for all kinetic runs at pH 3.5 using excess thione ligands with concentration of 2-10 mM. The reactions were carried out in the presence of 30 mM KCl to prevent the complex hydrolysis. All kinetic data are summarized in (Tables 7.3-7.6).

Plots of $\ln(A_{\infty}-A_t)$ versus time, at constant temperature, pH 3.5 and fixed concentration of complex (0.2 mM) with excess Tu or DIAZ, were observed as nonlinear as shown in Fig. 7.12. The nonlinear plots, initially curved and subsequently plateaued (Figs.7.14-7.16), support that the interactions proceeded through two consecutive steps, as shown in Scheme 24.

$$(A_{\infty} - A_t) - a_2 \exp(-k_{\text{obsd}2} t) = a_1 \exp(-k_{\text{obsd}1} t) \quad (1)$$

$$\Delta = a_1 \exp(-k_{\text{obsd}1} t) \quad (2)$$

Where, a_1 and a_2 are constants that are dependent on the rate constants and extinction coefficient (ϵ), and Δ values are the difference of $\ln(A_{\infty}-A_t)$ values between the observed and extrapolated part of the linear portion of the plot of $\ln(A_{\infty}-A_t)$ versus time (t). The values of $(A_{\infty}-A_t) - a_2 \exp(-k_{\text{obsd}2} t)$ are obtained from the difference of X-Y values at different time (Fig. 7.12) when time is 0-10 seconds (A_{∞} is the absorbance after reaction completion and A_t is absorbance at time t).

Figure 7.12. Kinetic plot of $\ln(A_{\infty}-A_t)$ versus time (sec); $[Au(cis-DACH)Cl_2]Cl = 2.0 \times 10^{-4} M$; $[DIAZ] = 5.0 \times 10^{-3} M$; in aqueous solutions containing 30 mM KCl, at pH 3.5 and 15 °C.

Evaluation of the rate constant k_1

The rate constant of the first step ($A \rightarrow B$ in Scheme 24) is dependent on the thione concentration, which is consistent with previous reports [61,192]. At constant temperature, the rate constant (k_{obsd1}) for reaction of Tu or DIAZ with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ were obtained from the slopes of the plots of $\ln \Delta$ versus time as illustrated in Figures (7.17-7.20).

Typical calculations were made for each thione at concentrations of 2 -10 mM, 0.2 mM of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]^+$ or $[\text{Au}(\text{cis-DACH})_2]^{3+}$, pH 3.5, in aqueous solutions containing 30 mM KCl and at different temperatures of 288.2, 298.2 and 310.2 K. k_{obsd1} values were calculated by the Weyh and Hamm method [206].

A plot of k_{obsd1} versus thione concentration gives a straight line with an intercept = k_{-1} and a slope = k_1 . As illustrated in Eq. 3,

$$k_{\text{obsd1}} = k_1[\text{thione}] + k_{-1}[\text{Cl}^-] \quad (3)$$

Evaluation of the rate constant k_2

The second step ($B \rightarrow C$ in Scheme 24) is a slower process than the first one due to competition between the second thione and the solvent. Kinetics showed that this step is independent on ligand concentration. The k_{obsd2} values were calculated from the slopes of the linear portion of the plots of $\ln(A_\infty - A_t)$ versus time.

A plot of k_{obsd2} versus thione concentration gave a straight line with an intercept = k_{-2} and a slope = k_2 as illustrated in Eq. 4.

$$k_{\text{obsd2}} = k_2[\text{thione}] + k_{-2}[\text{Cl}^-] \quad (4)$$

Plots of pseudo first-order rate constants as a function of thione concentration at different temperatures for the substitution reactions of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ or

$[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu and DIAZ are shown in Figs. (7.21-7.24). The rate constants (k_1 and k_2) are summarized in Table 7.7.

Evaluation of activation parameters

The activation parameters (ΔH^\ddagger , ΔS^\ddagger) for the reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ or $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with Tu and DIAZ were evaluated using Eyring plots. The Eyring plots for these substitution reactions at various temperatures are shown in Figures. (7.25-7.31). ΔH^\ddagger and ΔS^\ddagger values are summarized in Table 7.7. Enthalpies of activation are comparable to Ag-Cl and Ag-S bond energies and are consistent with previous studies [106]. Entropies of activations are all highly negatives, which support that all steps follow associative mechanisms. This is expected, at least for the Au(III) complexes. These d^8 Au(III) complexes are expected to show similar behavior to square planar Pt(II) complexes [2007-209].

Figure 7.13. UV-Vis spectra for the substitution reaction between $[\text{Au}(\text{cis-DACH})\text{Cl}_2]^+$ ($2.0 \times 10^{-4} \text{ M}$) with Tu ($2.0 \times 10^{-4} \text{ M}$), in aqueous solution containing 30 mM KCl, pH 3.5 at 298 K.

Figure 7.14. A typical kinetic trace for the substitution reaction between $[\text{Au}(\text{cis-DACH})\text{Cl}_2]^+$ ($10.0 \times 10^{-4} \text{ M}$) and Tu ($2.0 \times 10^{-3} \text{ M}$), in aqueous solution containing 30 mM KCl, pH 3.5 with wavelength 237nm and at 310 K.

Figure 7.15. A typical Kinetic trace for the substitution reaction between $[\text{Au}(\text{cis-DACH})_2]^{3+}$ ($2.0 \times 10^{-4} \text{ M}$) and Tu ($2.0 \times 10^{-3} \text{ M}$), in aqueous solution containing 30 mM KCl, at pH 3.5, wavelength 245 nm and at 288 K.

Figure 7.16. A typical kinetic trace for the substitution reaction between $[\text{Au}(\text{cis-DACH})_2]^{3+}$ ($2.0 \times 10^{-4} \text{ M}$) and DIAZ ($6.0 \times 10^{-3} \text{ M}$), in aqueous solution containing 30 mM KCl, at pH 3.5, wavelength 251 nm and 288 K.

Table 7.7 shows that the rate constant for the reaction of the two complexes with DIAZ and Tu. The reactivity of these thione ligands are shown to be slower than that for cyanide. It is also much faster than other nucleophiles as in these order: L-Histidine > guanosine-5'-monophosphate > inosine-5'-monophosphate > inosine towards the $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ complex [62].

Figure 7.17. A typical Kinetic plot of $\ln\Delta$ versus time (sec); $[Au(cis-DACH)Cl_2]Cl = 2.0 \times 10^{-4}M$; $[DIAZ] = 5.0 \times 10^{-3}M$; in the presence of 30 mM KCl, at pH 3.5 and 288 K.

Figure 7.18. A typical Kinetic trace of the plot $\ln\Delta$ versus time (sec) for the substitution reaction between $[Au(cis-DACH)Cl_2]^+$ ($10.0 \times 10^{-4} M$) and $Tu = 2.0 \times 10^{-3} M$, in aqueous solution containing 30 mM KCl, at pH 3.5, wavelength 237 nm and at 310 K.

CHAPTER 8

NMR AND KINETIC STUDIES OF THE INTERACTION OF [Au(*cis*-DACH)Cl₂]Cl AND [Au(*cis*-DACH)₂]Cl₃ WITH POTASSIUM CYANIDE IN AQUEOUS SOLUTION

8.1 Introduction

Recently, chemical and biochemical studies of Au(III) complexes containing N-chelating ligands have been reported showing biological activity [41, 68,210-215]. In addition, a number of other Au(III) complexes with N-ligands have been developed as promising anti-cancer and showed better cytotoxic activities. Gold(III) is analogue of the antitumor agent *cis*-diaminedichloroplatinum(II) (*cisplatin*) and in *cis*-1,2-diaminocyclohexane dichlorido- platinum(II) (DACH) complexes. The new gold(III) complexes may be attractive as anticancer drugs to overcome *cisplatin* side-effects [26, 188, 216-218].

Al-Maythaly et al. investigated the interaction of Au(III)–alkyldiamine complexes with L-histidine and imidazole ligands by ¹H, ¹³C NMR and UV spectrophotometry, and found that the rate of reaction is dependent on pH [101]. Zhu et al. reported the synthesis, structure and electrochemistry of Au(III) ethylenediamine complexes and their interactions with Guanosine5-phosphate [219]. Sanghvi et al. described antitumor properties of five-coordinate gold(III) complexes bearing substituted polypyridyl ligands, and found that [(*sec*-butyl)phen)AuCl₃] has more significant in vitro antitumor activity than

metallotherapeutic *cisplatin* [220]. Ahmed et al. studied histological changes in kidney and liver of rats due to exposure of $[\text{Au}(\text{en})\text{Cl}_2]\text{Cl}$ complex [8]. Al-Jaroudi et al. described the synthesis, characterization and cytotoxicity of gold(III) complexes with the ligand 1,2-diaminocyclohexane, and showed the influence of stereochemistry on antitumor activity [198]. Monim-ul-Mehboob et al. prepared a series of Au(III)-alkanediamine complexes, with ligands ethylenediamine, propylenediamine, butylenediamine, and N-alkyl substituted ethylenediamine, those were characterized and tested against gastric, prostate and ovarian cancer cells [221].

The interaction of Au(III) with cyanide ligand has interest in therapeutic values and pharmacological activity, due to the formation of $[\text{Au}(\text{CN})_4]^-$, which is unstable in physiological condition and produces $[\text{Au}(\text{CN})_2]^-$. Cyanide is naturally produced in the body by oxidation of SCN^- by the enzyme myeloperoxidase (MPO) and released by phagocytic cells [50, 203, 222]. The $[\text{Au}(\text{CN})_2]^-$ has been extensively used in the treatment of rheumatoid arthritis since 1920s, while other Au(I) complexes showed activity against malaria and HIV [52, 109].

Canumalla et al. described redox and ligand exchange reactions of potential gold(I) and gold(III)-cyanide metabolites under biomimetic conditions [195]. Yangyuoru et al. studied the reduction of auricyanide using biological ligand glutathione (GSH) as reductant through two intermediates I_{230} and I_{290} [194]. Al-Maythaly et al. described ^1H , ^{13}C NMR and UV-Vis spectroscopy studies of gold(III)-tetracyanide complex with L-cysteine, glutathione, captopril, L-methionine and DL-seleno-methionine in aqueous solution [101].

8.2 Experimental section

8.2.1 Materials and instrumentation

NaAuCl₄.2H₂O, *cis*-DACH (C₆H₁₄N₂) were purchased from Sigma-Aldrich- USA, absolute ethanol from Merck, CH₃OD and D₂O were purchased from Alfa-Aesar, KCN, 99.9% enriched K¹³CN and 99% enriched K¹³C¹⁵N from Cambridge Isotope Lab. Inc. Deionized water with a resistivity of 18.6 MΩ cm⁻¹ is used to prepare all solutions. The water is obtained directly from a PURELABs Ultra Laboratory Water Purification System. Spectroscopic and electrochemical techniques, synthesis of [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ were described in section 3.1.

8.2.2 Kinetic Measurements

The UV-Vis spectra of the complex and cyanide solutions were recorded over the range 200-500 nm, Fig. 8.1 (five runs) and are showing λ_{\max} at 305 nm and 258 nm for [Au(*cis*-DACH)Cl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ respectively. The reactions were started by mixing the complex and cyanide solutions in equal volumes directly in a vial kept inside the instrument. The kinetic measurements were made under pseudo-first order conditions, where concentration of the complex is 0.1 mM and for the cyanide it was in the range 2-10 and 20 mM. The reactions were followed over 10 minutes and were carried out at ambient temperature of 25 °C. The pseudo-first order rate constant k_{obsd} is calculated as an average value of eight independent kinetic runs [61]. Observed experimental data are reported in Table 8.5.

Figure 8.1. The UV-Vis spectra for the substitution reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ ($1.0 \times 10^{-4} \text{M}$) (a) before and (b) after addition of cyanide ($5.0 \times 10^{-3} \text{M}$) and (c) cyanide before reaction, the substitution reaction carried out at ambient temperature of 25°C .

8.3 Results and Discussion

8.3.1 Interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ With K^{13}CN

Interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with enriched KCN was carried out in CH_3OD by mixing the reactants at different ratios and monitored by ^1H , ^{13}C , ^{15}N NMR, UV-Vis spectroscopy and electrochemistry. ^1H , ^{13}C and ^{15}N NMR chemical shifts for the species in this interaction are given in Tables (8.1-8.2, 8.4A) .

When ^{13}C NMR is used to monitor the reaction, (Fig.8.2a) shows the chemical shift of (5 mM) 20% enriched K^{13}CN at 160.48 ppm. The peak at 103 ppm in (Fig.8.2b) indicates the white precipitate $[\text{Au} (^{13}\text{CN})_4]^-$. It is formed by interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with K^{13}CN at (1:0.25) ratio, and consistent with the data reported in previous studies [101,195, 223].

Table 8.1. ^1H NMR chemical shifts of the reaction of $[\text{Au}(\text{cis-DACH})(\text{Cl}_2)\text{Cl}]$ complex with K^{13}CN ligand in CH_3OD solution.

Specie	1H, 2H	3H, 6H eq	3H, 6H ex	4H, 5H eq	4H, 5H ex
(1: 0)	3.59 m	2.02 m	1.76 m	1.47 m	1.29 m
(1: 1)	3.56 m	2.00 m	1.75 m	1.48 m	-
(1: 2)	3.39 m	1.87 m	1.62 m	1.40 m	0.86 m
(1: 4)	3.61 m	1.76 m	1.51 m	1.32 m	0.86 m

The anionic complex, $[\text{Au}^{(13}\text{CN})_4]^-$ is not stable and goes, through *trans*-effect, into reductive elimination to form cyanogen (NCCN), which appeared at 110.52 ppm, while Au(III) was reduced to $[\text{Au}^{(13}\text{CN})_2]^-$, which was shifted up-field at 152-157 ppm, due to the back donation of gold to cyanide ligand [205]. The $[\text{Au}(\text{CN})_2]^-$ complex has higher stability due to its significant covalent bond than the corresponding $[\text{Cu}(\text{CN})_2]^-$ and $[\text{Ag}(\text{CN})_2]^-$ described by Wang et al [224].

Figure 8.2c shows the ^{13}C spectrum, where the two peaks at 101.31 ppm and 96.50 ppm, indicate the rapid consecutive exchange of chloride ions by $^{13}\text{CN}^-$ ion to produce $[\text{Au}(\text{cis-DACH})(^{13}\text{CN})\text{Cl}]^-$ and $[\text{Au}(\text{cis-DACH})(^{13}\text{CN})_2]^-$ respectively. The down-field shift at (1:1.5) ratio to 119.13 ppm, 120.52 ppm, and 121.34 ppm indicates the formation of $[\text{Au}(\text{CN})_2\text{Cl}_2]^-$, $[\text{Au}(\text{CN})_3\text{Cl}]^-$, and $[\text{Au}^{(13}\text{CN})_2(\text{OH})\text{Cl}]^-$ respectively. While the peak at 137 ppm indicates HCN generated by 99.9 % hydrolysis of K^{13}CN [101].

The ^{13}C spectrum, fig.2d sheds a light on another reaction mechanism of the reduction of $[\text{Au}(^{13}\text{CN})_4]^-$ to $[\text{Au}(^{13}\text{CN})_2]^-$ through intermediate complexes $[\text{Au}(^{13}\text{CN})_2\text{Cl}_2]^-$, $[\text{Au}(^{13}\text{CN})_3\text{Cl}]^-$, and $[\text{Au}(^{13}\text{CN})_2(\text{OH})\text{Cl}]^-$ by displacement of cyanide by chloride through *cis* effect kinetics, unlike the behaviour of Pt(II) described by Skibsted [225].

Scheme 26. Suggested mechanism of conversion $[\text{Au}(^{13}\text{CN})_4]^-$ to $[\text{Au}(^{13}\text{CN})_2]^-$.

The above mechanism is the solvolytic pathway through reversible exchange of chloride and H_2O . For instance, H_2O is being the stronger compared to chloride and cyanide ions in spectrochemical series [226]

Figure 8.2. ^{13}C NMR spectra of (a) free K^{13}CN , (b) after reaction with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ at (1: 0.25) ratio, (c) at (1: 0.5) ratio, (d) at (1: 1.5) ratio and (e) at (1: 2) ratio, in CH_3OD .

The CN^- ion, being the strong π -acceptor rapidly displaces DACH at (1:2) ratio as shown by the resonance of free DACH at 53.03 ppm, 31.03 ppm, 22.95 ppm (Fig.2e) [194]. Table 8.1 shows ^1H NMR chemical shifts of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ complex interacting with CN^- ligand at different ratios. (Fig. 8.3a) shows a peak at 265 ppm assigned to (5 mM) free 99.9 % enriched $\text{K}^{13}\text{C}^{15}\text{N}$. for the ration reaction (1:2) (Fig.3b) this peak shifted down-field at 281 ppm and it is assigned to $[\text{Au}^{(13}\text{C}^{15}\text{N})_4]^-$. While at (1:4) ratio, (Fig. 8.3c) there are two resonances at 262 ppm and at 281 assigned to $[\text{Au}^{(13}\text{C}^{15}\text{N})_2]^-$ and $[\text{Au}^{(13}\text{C}^{15}\text{N})_4]^-$ respectively [205].

Figure 8.3. ^{15}N NMR spectra of (a) free $\text{K}^{13}\text{C}^{15}\text{N}$, (b) after reaction with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ at (complex: ligand) (1:2) ratio, (c) after reaction with $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ at (complex: ligand) (1:4) ratio, in CH_3OD .

Moreover, the obtained electrochemical results came in a complete agreement with ^1H , ^{13}C , and ^{15}N NMR and UV spectroscopy, and confirmed the suggested mechanism (Schemes 25 and 26). Figure 8.4 and its inset show the SWVs obtained at the GCE

(glassy carbon electrode) in a quiescent aqueous solution of 0.2 M KCl. A well-defined SWV peak (Fig. 8.4b) was obtained at +0.82V (vs. Ag/AgCl) for 1.0 mM $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$. This peak showed a systematic decrease on its peak area with subsequent additions of CN^- at different equivalents (1:0.5), (1:1) and (1:1.5) (Fig. 4 c-e). At (1:2) ratio, a complete peak disappearance was observed with the appearance of a new peak shoulder around +1.4V (Fig.8.4f), which became more defined at (1:3) and (1:4) ratios. The same additions of CN^- to 0.2 M KCl solution in absence of the $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ complex showed no peaks (data not shown).

Figure 8.4. SWVs in a 0.2 M KCl aqueous solution at a GCE in absence (a) and presence (b) of 1.0 mM $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$, and subsequent additions of 0.5 mM (c-f) and 1.0 mM (g, h) of KCN aqueous solution. Working condition of the pulse width (increment), 4mV; pulse height (amplitude), 25 mV; frequency, 15 Hz. Inset is the corresponding histogram at different complex: CN^- ratio.

8.3.2 Interaction of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with K^{13}CN

Interaction of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with 20% enriched K^{13}CN was carried out in D_2O by mixing the reactants at different mole ratios and monitored by ^1H , ^{13}C , ^{15}N NMR, UV-vis spectroscopy, and electrochemistry. The ^1H , ^{13}C and ^{15}N NMR chemical shifts for this interaction are given in Tables (8.3-8.4B). ^{13}C NMR is used to monitor the interaction, (Fig. 8.5a) shows a peak for (5 mM) 20% enriched K^{13}CN assigned at 157.4 ppm. (Fig. 8.5b) shows two new peaks up-field at 104.5 ppm and at 119.8 ppm corresponding to $[\text{Au}^{(13}\text{CN})_4]^-$ and $[\text{Au}(\text{CN})_2\text{Cl}_2]^-$ respectively [101,195]. When the reaction is carried out at (1:1) ratio, the peak at 119.8 ppm is shifted down-field 120.47 ppm and a new peak is observed at 154.37 ppm, assigned to $[\text{Au}^{(13}\text{CN})_2]^-$, which is the result of reductive elimination of $[\text{Au}^{(13}\text{CN})_4]^-$ (Fig. 8.5c) [223].

Figure 8.5d shows a peak at 110.10 ppm of cyanogen (NCCN) due to an oxidation of CN^- and reduction of Au(III) to Au(I) [101]. There is a significant down-field shift from 119.8 ppm to 122.5 ppm corresponding to very fast consecutive two cyanide ligands exchanged by H_2O due to solvolytic pathway [226].

Table 8.3. ^1H NMR chemical shifts of DACH protons for the reaction of $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with (K^{13}CN) in D_2O .

Species	1H, 2H	3H, 6H eq.	3H, 6H ex.	4H, 5H eq.	4H, 5H ex.
(1:0)	3.58 m	1.94 m	1.74 m	1.56 m	1.38 m
(1:1)	3.32, 3.20 m	1.86 m	1.65 m	1.53 m	1.33 m
(1:2)	3.21, 3.06 m	1.80 m	1.62 m	1.49 m	1.26 m
(1:4)	3.75, 2.85 m	-	1.65 m	1.42 m	1.23 m

Figure 8.5. ^{13}C NMR spectra of (a) free K^{13}CN , (b) after reaction with $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at (1: 0.25) ratio, (c) at (1:1) ratio, (d) at (1: 2) ratio in D_2O .

At higher concentration of $^{13}\text{CN}^-$ ion into (1:4) ratio, an up-field shift of DACH's carbons was observed, which corresponds to the displacement of DACH ligands. The peak observed at 121 ppm is an indication of H_2O being exchanged by chloride to form $[\text{Au}(\text{CN})_2(\text{OH})\text{Cl}]^-$ (Fig. 8.5d) [195]. Table 8.3 shows ^1H NMR chemical shifts for $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ reaction with K^{13}CN in the range (1:1) to (1:4) ratio.

Table 8.4(A-B). ^{15}N NMR chemical Shifts of the $^{13}\text{C}^{15}\text{N}^-$ for different species during the reactions of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (A) and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ (B) with $\text{K}^{13}\text{C}^{15}\text{N}$ in CH_3OD and D_2O .

Specie	A	B
$\text{K}^{13}\text{C}^{15}\text{N}$	265.03 ppm	271.82 ppm
$[\text{Au}(^{13}\text{C}^{15}\text{N})_2]^-$	262.63 ppm	265.06 ppm
$[\text{Au}(^{13}\text{C}^{15}\text{N})_4]^-$	281.52 ppm	275.01 ppm

The ^{15}N NMR spectrum (Fig.8.6b) shows two resonances at 275.01 ppm and 265.06 ppm assigned to $[\text{Au}(^{13}\text{C}^{15}\text{N})_4]^-$ and $[\text{Au}(^{13}\text{C}^{15}\text{N})_2]^-$ respectively.

Figure 8.7 shows a SWV peak for the $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at +1.35V (vs. Ag/AgCl). The peak area decreased systematically with the additions of CN^- . However, and due to the relatively high potential peak position (+1.35V), the decrease was not easy to follow, yet the trend is clear.

Figure 8.6. ^{15}N NMR spectra of (a) free $\text{K}^{13}\text{C}^{15}\text{N}$ and (b) after reaction with $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ at (complex: ligand) (1:2) ratio in D_2O .

Figure 8.7. SWVs in a 0.2 M KCl aqueous solution at a GCE in absence of complex (a) and presence (b) of 1.0 mM $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$, and subsequent additions of 0.5 mM (c-f) and 1.0 mM (g, h) of KCN aqueous solution. Working condition of the pulse width (increment), 4 mV; pulse height (amplitude), 25 mV; frequency, 15 Hz.

8.3.3 Kinetic Data

The substitution reactions of these square-planar gold(III) complexes [(*cis*-DACH)AuCl₂]Cl and [Au(*cis*-DACH)₂]Cl₃ with cyanide ion were investigated spectrophotometrically by the change of absorbance at the selected wavelengths as function of time under pseudo-first order conditions. The substitution reaction proceeds most likely through an associative mechanism. All reactions were studied in aqueous solution. An addition of 20 mM NaCl prevents hydrolysis of the complex. The suggested reaction mechanism of cyanide ion with [Au(*cis*-DACH)Cl₂]Cl is shown in Scheme 25. The rate constants are determined from the plot of linear dependence of k_{obsd} versus total cyanide concentration (figure 8.8A) according to equation (1). The slope of the line represents k_f , while the intercept indicates $k_b[\text{Cl}^-]$. All kinetic data are summarized in Table 8.5.

$$k_{\text{obsd}} = k_f[\text{CN}^-] + k_b[\text{Cl}^-] \quad (1)$$

The Enthalpy, Entropy and Activation energy for the reaction of [Au(*cis*-DACH)Cl₂]Cl with cyanide ion are calculated using Eyring equation (2) and Arrhenius equation (3)

$$\ln \frac{k}{T} = \frac{-\Delta H^\ddagger}{R} \cdot \frac{1}{T} + \ln \frac{k_B}{h} + \frac{\Delta S^\ddagger}{R} \quad (2)$$

$$\ln(k) = \ln(A) - \frac{E_a}{R} \frac{1}{T} \quad (3)$$

From the rate constant values, it can be clearly seen that the $[\text{Au}(\textit{cis}\text{-DACH})\text{Cl}_2]\text{Cl}$ reacts much faster than $[\text{Au}(\textit{cis}\text{-DACH})_2]\text{Cl}_3$ complex. The difference in reactivity can be attributed most likely to the lability of chloride and the chelate of two (*cis*-DACH) ligands [223].

Table 8.5. Rate constant k , for substitution reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with cyanide ion, in the presence of 20 mM NaCl in aqueous solution at 298 K.

The reactive kinetics of the cyanide ligand is found to be much faster than the following nucleophiles: L-histidine (L-His), guanine-5'-monophosphate (5'-GMP), inosine (Ino), and inosine-5'-monophosphate (5'-IMP) towards the $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ complex [61-62].

The reactivity order of these ligands toward $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ complex is $\text{CN}^- \gg \text{L-His} > 5'\text{-GMP} > \text{Ino} > 5'\text{-IMP}$ as shown in (Table 8.6). it is substitution reaction and absorbance band is 305 nm as shown in Fig. 8.9.

Table 8.6. Rate constants for substitution reactions of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ complexes with cyanide in presence of 20 mM NaCl in aqueous solution at 298K.

Figure 8.10 shows UV spectra of an oxidation reduction reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with CN^- ion at (complex: ligand) (1:2) ratio. The bands observed at 204 nm and 211 nm, correspond to $[\text{Au}(\text{CN})_2]^-$, by the back donation from d-orbital(d^8) in Au(III) ion to empty π^* -acceptor in cyanide ligand, which strengthens Au-CN and weakens Au-NR. Figure 8.11 shows an oxidation reduction reaction of

$[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with CN^- ion at (1: 4) ratio. The bands observed at 204, 211 and 240 nm assigned to $[\text{Au}(\text{CN})_2]^-$, remains unchanged after 24 h, indicating completion of the oxidation reduction reaction [228-229]. Figure 8.12(A-B) show pseudo-first order rate constant as function of nucleophilic concentration and temperature for the reaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with cyanide ion.

Figure 8.8A. Plot of pseudo-first order rate constant for the reaction between $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ with cyanide ion in aqueous solution at ambient temperature of 25 °C.

Figure 8.8B. Plot of pseudo-first order rate constant for the reaction between $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with cyanide ion in aqueous solution at ambient temperature of 25 °C.

Figure 8.9. UV-Vis spectra for the substitution reaction of (a) $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (1 mM) before and (b) after addition of KCN (1 mM) at (complex: ligand) (1:0.5) ratio in the range 240-400 nm at ambient temperature of 25 °C.

Figure 8-10. UV-Vis spectra for an oxidation reduction reaction of (a) $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (0.1 mM) before and (b) after addition of KCN (0.1 mM) at (complex: ligand) (1:2) mole ratio in the range 200-350 nm at 25 °C.

Figure 8.11. UV-Vis spectra for an oxidation reduction reaction of (a) $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ (0.1 mM) before and (b) after 30 min of addition of KCN (0.1 mM) at (complex: ligand) (1:4) mole ratio in the range 200-350 nm at 25 °C.

Figure 8.12A: Plot of pseudo first order rate constants, as function of CN^- concentration and temperature for the reaction between $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and cyanide ion in the presence of 20 mM NaCl in aqueous solution.

Figure 8.12B: Plot of pseudo first order rate constants, as function of CN^- concentration and temperature for the reaction between $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ and cyanide ion in the presence of 20 mM NaCl in aqueous solution.

CONCLUSION AND FUTURE STUDIES

Gold(I) complexes belong to an emerging class of potential anticancer agents. During the past couple of decades many gold(I) compounds with versatile structures, showing promising cytotoxic effects against selected human cancer cell lines and acceptable stability under physiological conditions have been reported. All attributes make them good candidates as antitumor drugs. Herein, we report the synthesis, and characterization of gold(I) complexes $[\text{Au}(\text{R}_3\text{P})(\text{R}_2\text{NCS}_2)]$ (**2-34**); $[\text{Au}(\text{R}_3\text{P})_2]$ (**35-37**); $[\text{Au}(\text{Ipr})-(\text{Se}=\text{CR}_2)]$ (**38-50**); $[\text{Au}(\text{R}_3\text{P})(\text{S}=\text{CR}_2)]$, (**51-55**), $[\text{Au}(\text{Ipr})(\text{R}_3\text{P})]$ and $[\text{Au}(\text{Ipr})_2(\text{R}_6\text{P}_2)]$ (**56-65**). Compounds (**2-22**), (**35-37**), and (**38-50**) were tested for their *in vitro* cytotoxicity against three human cancer cell lines; HeLa (human cervical cell line), HCT 15 (human colon cell line) and A549 (human lung carcinoma). Gold(I) compounds (**20-22**, **48**) exhibited better cytotoxicity in terms of IC_{50} values against A549 cell line and HCT15 than the standard anticancer chemotherapy drug (cisplatin). Whereas, the other studied gold(I) compounds showed moderate to lower *in vitro* cytotoxicity against HCT15 and HeLa cancer cell lines. The significant cytotoxicity of gold(I) compounds against A549 and HCT15 human cancer cells has made them strong candidates as potential anticancer agents for further exploration against lung and colon cancer.

The interaction of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with cyanide, Tu and DIAZ was studied using (^1H , ^{13}C and ^{15}N) NMR and square wave stripping voltammetry. contribution for DaipSe and DaizSe relatively to ImSe due to ring strain hindering the rehybridization of N culminating in DaipSe NMR studies showed that DIAZ ligates more strongly than Tu. Thiol form be as a higher contribution for DIAZ than thione relatively

to Tu (evident from the magnitude of (C=S) chemical shift). Kinetic measurements revealed that the substitutive reaction $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ reacting faster than $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$. Also the trend of the rate constants for the ligands order as following: cyanide $\gg \gg$ Tu $>$ DIAZ. The negative values of ΔS^\ddagger for these reactions lend support for an associative mechanism and these results may contribute to a better understanding of biochemical mechanism of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$.

For further future studies

- ✓ *In vitro* cytotoxicity assay of the compounds (**23-34**), (**51-55**) and (**56-65**).
- ✓ *In vivo* assay for gold(I) compounds with the significant cytotoxicity to explore their mechanism of action.
- ✓ Stopped flow kinetics of $[\text{Au}(\text{cis-DACH})\text{Cl}_2]\text{Cl}$ and $[\text{Au}(\text{cis-DACH})_2]\text{Cl}_3$ with biomolecules.

VITAE

Name : Adam Ahmed Abdallah Sulaiman

Nationality : Sudanese

Date of Birth : December 31, 1979

E-mail : adamahmed@kfupm.edu.sa, adamchemi@gmail.com.

Address : KFUPM, Dhahran 31261, Saudi Arabia

Academic Background : B.Sc.(Hon.), AL-Neelain University, Sudan
M.Sc. in Applied Chemistry, University of Gezira, Sudan

PATENTS

1. Anvarhusein A. Isab, Muhammad Altaf, M. Monim-ul-Mehboob, **Adam A.A. Seliman** New gold(I) complexes with t-butyl phosphine and dialkyl dithiocarbamate ligands, *US Patent 0266909A1*, 2015.

CONFERENCE PAPERS

1. **Adam A. A. Seliman** and A. A. Isab, “New Gold(I) Complexes with t-butyl phosphine and Dialkyl-dithiocarbamate Ligands: Synthesis, Spectroscopic Characterization, and In vitro Cytotoxic Evaluation against A549, HeLa New Gold(I) Complexes with t-butyl phosphine and Dialkyldithiocarbamate Ligands” the 5th Scientific Conference for Students of Higher Education, Riyadh, KSA, April 28 to May 2, 2014.
2. **Adam A. A. Seliman** and A. A. Isab, “NMR and kinetic studies of the interactions of [Au(cis-DACH)Cl₂]Cl and [Au(cis-DACH)₂]Cl₃ with potassium cyanide in aqueous solution” 3rd International Conference and Exhibition on Laboratory Technology (IABTECH), Manama, Kingdom of Bahrain, Oct, 28-30, 2014.

Awards

- The 5th Scientific Conference for Students of Higher Education, Riyadh, KSA, May, 2014

APPENDIX

Scheme 1: Some gold(I) complexes are used in rheumatic arthritis treatment.....	5
Scheme 2: Gold(I) phosphine anticancer drug (GoPI).....	5
Scheme 3: Basic imidazole structure (both N1 and N3 has one lone pair each)	11
Scheme 4: Thioamide ligands.....	15
Scheme 5: Oxidation of methionine residue in Gly-Met dipeptide in the presence of [Au(en)Cl ₂] ⁺	16
Scheme 6: Gold(I) with mono phosphine and dithiocarbamate complexes (1-3), gold(I) with (bis-phosphino)alkyl and dithiocarbamate complexes(4-12).....	19
Scheme 7: Mono and binuclear gold(I)phosphine complexes containing monoanionic seleno and thiosemicarbazone ligands.....	21
Scheme 8: Reaction scheme of complexes from (2-7)	22
Scheme 9: Synthesis of different Au(I)-NHC compounds bearing pentafluorophenol ester moiety.....	23
Scheme 10: Synthesis of different Au(I)-NHC compounds through reaction of activated ester moiety.....	24
Scheme 11: (a) Synthesis of compound 1 (b) Synthesis of compound 2.....	24
Scheme 12: Synthesis of gold(I) bis-phosphine complexes (1-5).....	25
Scheme 13: Synthesis of gold(I) bis-phosphine complexes (6-9).....	33

Scheme 14: Synthesis of gold(I) bis-phosphine complexes (10-13).....	36
Scheme 15: Synthesis of gold(I) bis-phosphine complexes (14-17).....	39
Scheme 16: Synthesis of gold(I) polymers (19-21) and gold(I) monophosphine complexes 18 and 22.....	42
Scheme 17: Synthesis of gold(I) mono-phosphine complexes (23-26).....	45
Scheme 18: Synthesis of gold(I) mono-phosphine complexes (27-30).....	48
Scheme 19: Synthesis of gold(I) mono-phosphine complexes (31-34).....	52
Scheme 20: Synthesis of gold(I)-phosphine complexes (35-37).....	54
Scheme 21: Synthesis of gold(I)-selone complex (39-50).....	85
Scheme 22: Synthesis of (tri-tert-butylphosphino)gold(I) with thione complexes (52-55).	
Scheme 23: Synthesis of gold(I)-carbene with mono and bis-phosphine complexes (56-65).....	126
Scheme 24: Proposed reaction pathways for the substitution reaction of: (A) [Au(cis-DACH)Cl ₂]Cl, (B) [Au(cis-DACH) ₂] ³⁺ with Tu and DIAZ in aqueous solution at pH 3.5.....	164
Scheme 25: Suggested mechanism reaction of [Au(cis-DACH)Cl ₂]Cl with K ¹³ CN in the range of (1:0.25) to (1:4) ratios.....	187
Scheme 26: Suggested mechanism of conversion [Au(¹³ CN) ₄] ⁻ to [Au(¹³ CN) ₂] ⁻	188
